

無線網路多媒體系統 Wireless Multimedia System

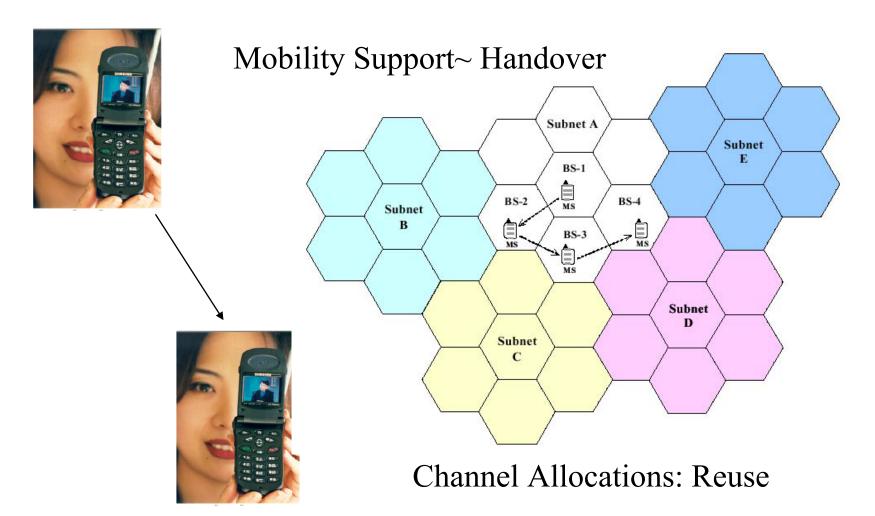

Lecture 3: Cellular Concepts 中央大學 吳曉光博士 http://wmlab.csie.ncu.edu.tw/course/wms

Mobility Support & Channel Reuse

Channel Assignment in Cellular System

- Fundamental Problem:
- Fixed Channel Assignment
- Dynamic Channel Assignment
- Hybrid Schemes
- Whole Channel Usage (CDMA)
- Reduce the Cell Size

Hand-off in Cellular Networks

- Transfer of mobile to a new channel when it crosses cell boundary
- Handoff delay
- Prioritizing handoffs to reduce probability of dropped calls
- Handoff Strategies
- Network Controlled handoff (NCHO)
- Mobile assisted handoff (MAHO)
- Mobile controlled handoff (MCHO)

Agenda

- Cellular Concepts
- Channel Assignments
- Handover
- Next Lecture: 3G WCDMA design

Reading

- [Katzela96]Katzela, and M. Nahgshineh,"Channel assignment schemes for cellular mobile telecommunication systems: a comprehensive survey," IEEE Personal Communications, June 1996
- [Pollinin96], G.P. Pollini, "Trends in handover design, "IEEE Communications Magazine, March 1996.

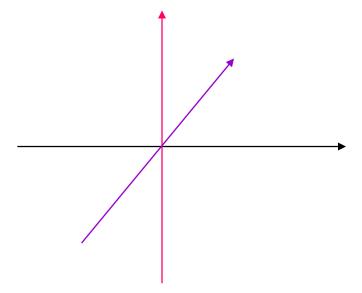

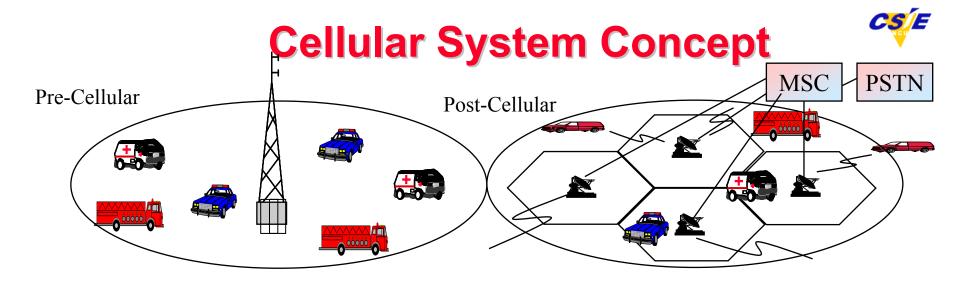

Channel Allocation

- A given Channel Spectrum (or bandwidth) can be divided into a set of disjoint or non-interfering radio channel
 - Frequency Division
 - frequency band
 - Time Division
 - time slot
 - Code Division
 - modulation code

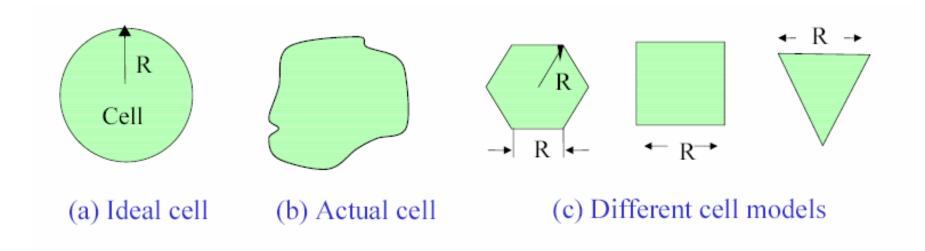

- Replace single high power transmitter covering the entire service area with low power
 - Mobiles in sufficiently distant base-stations may be assigned identical channel (frequency, time slot, & code)
 - System capacity may be increased without adding more spectrum
- Major conceptual breakthrough in spectra congestion & user capacity
 - Required relatively minor technological changes frequency reuse & cochannel interference, channel allocation, hand-offs

Cell Shape

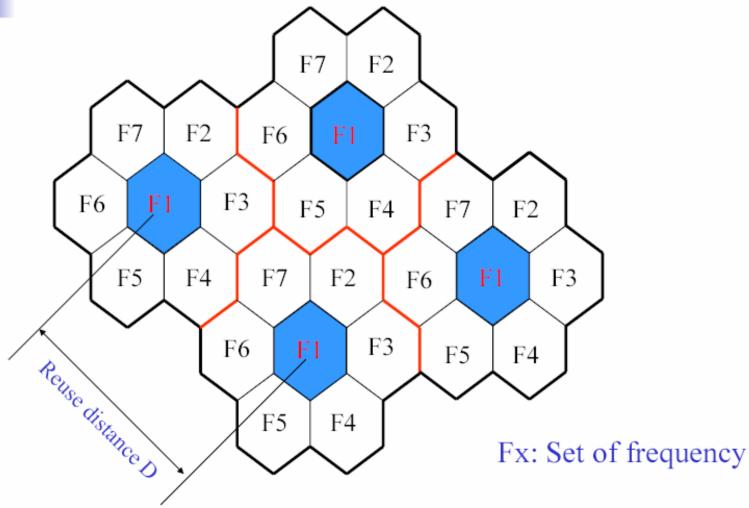

Frequency Reuse

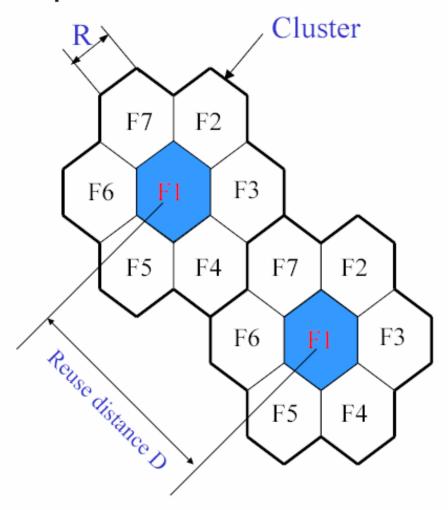

7 cell reuse cluster

Reuse Distance

• For hexagonal cells, the reuse distance is given by

$$D = \sqrt{3N}R$$

where *R* is cell radius and *N* is the reuse pattern (the cluster size or the number of cells per cluster).

· Reuse factor is

$$\frac{D}{R} = \sqrt{3N}$$

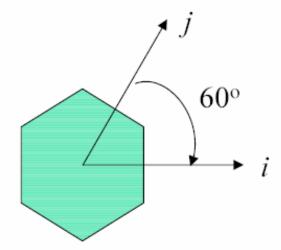

Reuse Distance (Cont'd)

■ The cluster size or the number of cells per cluster is given by

$$N = i^2 + ij + j^2$$

where *i* and *j* are integers.

N = 1, 3, 4, 7, 9, 12, 13, 16, 19, 21, 28, ..., etc.

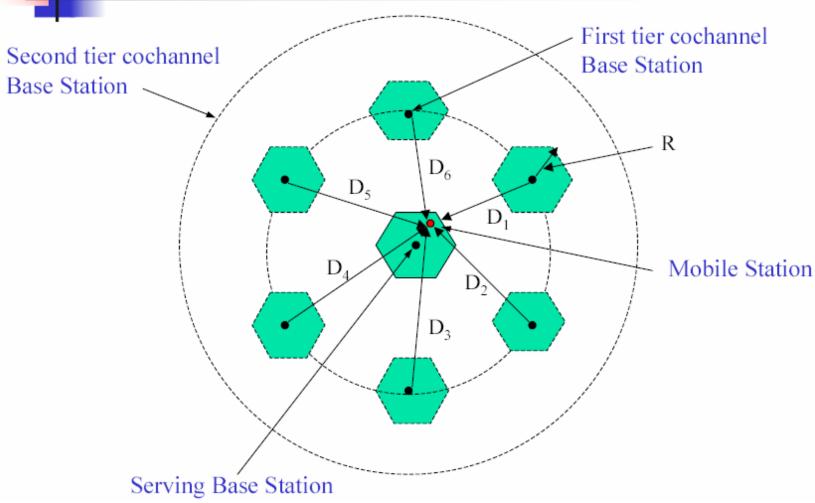

The popular value of *N* being 4 and 7.

Cochannel Interference

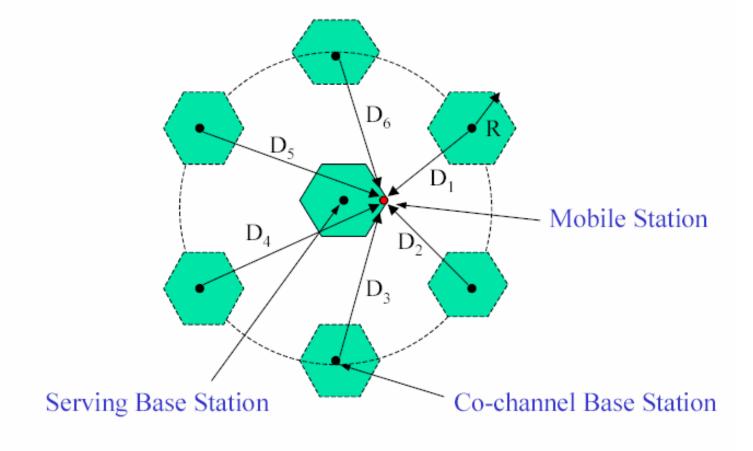

Worst Case of Cochannel Interference

Cochannel Interference

Cochannel interference ratio is given by

$$\frac{C}{I} = \frac{Carrier}{Interference} = \frac{C}{\sum_{k=1}^{M} I_k}$$

where I is co-channel interference and M is the maximum number of co-channel interfering cells.

For M = 6, C/I is given by

$$\frac{C}{I} = \frac{C}{\sum_{k=1}^{6} \left(\frac{D_k}{R}\right)^{\gamma}}$$

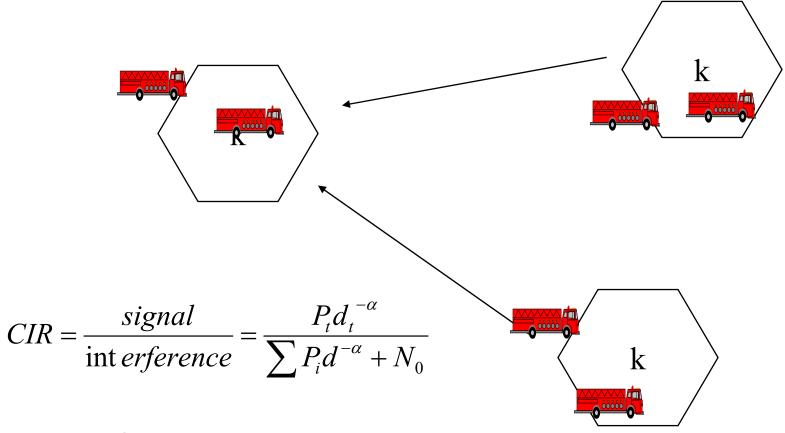

where γ is the propagation path loss slope and $\gamma = 2 \sim 5$.

Channel Reuse

 The same channel is reused simultaneously by other sets (Cochannel)

Wirelesso Multimedia

Interference

$$CIR = \frac{signal}{\text{int erference}} = \frac{P_{t}d_{t}^{-\alpha}}{\sum_{1}^{5}P_{i}d_{i}^{-\alpha} + N_{0}}$$

How to improve CIR (Quality)

- Increase the transmitting power (Power Control)
- Increase the separating distance (Channel Reuse)

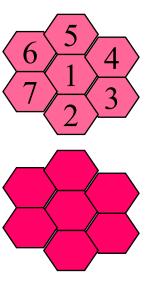

$$CIR = \frac{signal}{\text{int erference}} = \frac{P_t d_t^{-\alpha}}{\sum P_i d^{\alpha} N_0}$$

Approaches

- Fixed no flexibility
- Dynamic complexity
- Hybrid might be ok

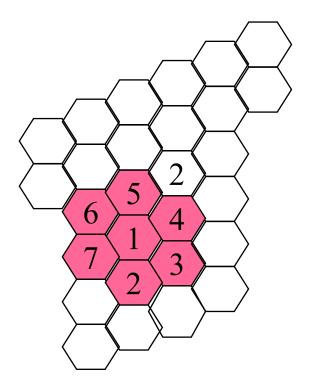

Frequency Reuse

Idealized grid of Hexagonal cells

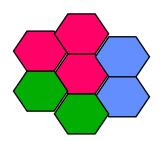

- Each BS is allocated a subset of carrier freqs
- Nearby BSs are allocated a different subset to avoid interference
- The total set is allocated to a small tesselating group of N neighboring BSs
 - Called "reuse cluster"
 - 1/N is the "reuse factor"
 - System capacity goes up by $\frac{N \times Area_{cell}}{N \times Area_{cell}}$
- Used in FDMA & TDMA based systems
 - Not required in CDMA which has universal frequency reuse
- Cells idealized as hexagons
 - Real cell footprints are amorphous
 - Hexagon close to a circle
 - Not appropriate for micro-cells, highways etc.

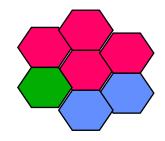

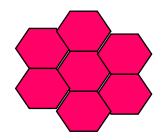

Reuse Cluster For Hexagonal Cells

 A tessellating group of N hexagonal cells is possibly only iff

- Frequency Reuse Distance D
 - minimum distance between centers of co-channel cells
 - Depends on # of nearby cochannel cells, terrain, antenna height, transmit power etc.
 - for hexagonal cells, $D = R \sqrt{3 N}$
 - Where, R is the radius of hexagon (center to vertices)
 - Increasing N, and therefore D, reduce co-channel interference (assuming R and transmit power are invariant
 - D/R is called the co-channel reuse ratio

Determining Cluster Size

- If N is reduced while cell area is kept constant
 - more cluster needed to cover the service area
 - more channels per cell
 - more system capacity achieved
 - more co-channel interference co-channel cells are closer
- Goal is to maximize system capacity (or, capacity per unit area) subject to interference limitations
 - Minimum N such that carrier-to-interference ratio
 - $C/I \ge (C/I)_{min}$
 - Reverse co-channel interference
 - Interference at a BS from co-channel MHs in other BSs
 - Forward co-channel interference
 - Interference at a MH from other co-channel BSs.
 - Adjacent channel interference
 - From signals in adjacent channel due to imperfect filters
 - Don't assign adjacent frequencies to the same cell and if possible immediate neighbors

Determining Cluster Size N

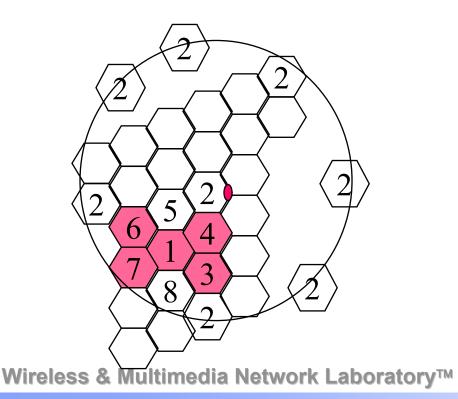

- Goal is maximize system capacity (or, capacity per unit area) subject to interference limitations
 - minimum N such that carrier-to-interference ratio
 - ◆ C/I >= (C/I)_{min}
 - reverse co-channel interference
 - interference at BS from co-channel MHs in other BSs.
 - forward co-channel interference
 - interference at a MH from other co-channel BSs
 - adjacent channel interference
 - from signals in adjacent channels due to imperfect filters

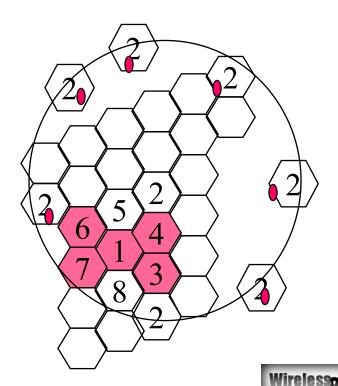

Calculating C/I

- Let i_0 be the number of co-interfering cells, and noise be negligible $\underline{C}_=$
 - C/I = Carrier / All of the co-channel interference
 - Where C is the desired carrier power and I_i is the signal power of i-th interferer

Calculating C/I

• Recall:
$$P_r(d) = P_r(d_0) \left(\frac{d}{d_0}\right)^n$$

- For equal transmit powers and path loss exponents: $\frac{C}{I} = \frac{D_0^{-n}}{\sum_{i=1}^{l_0} D_i^{-n}}$
- Assume:
 - 1. n=4
 - 2. worst case is at $D_0 = R$ (when MH is at the fringe of its cell)
 - 3. only the six "first-tier" co-channel cells are considered

• 4.
$$D_1 = D_2 = D_3 = D_4 = D_5 = D_6 = D$$

C/I~ (D/R)⁴ / 6 depends only on the ratio D/R

system	(C/I) _{min}	D/R	N
AMPS	18 dB	4.6	7
GSM	11 dB	3.0	4

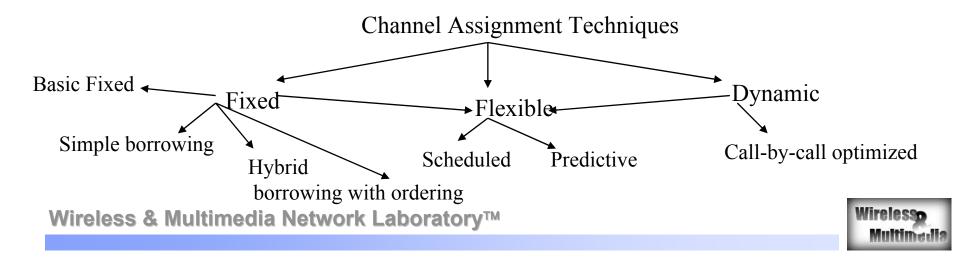

Microcells-Reducing Cell Area

- IF cell area is reduced while N is kept constant
 - more clusters needed to cover the service aread
 - C/I is unchanged because D/R is unchanged
 - system capacity grows quadratically with radius scale factor
- Small cells need lower RF transmitted power
 - longer battery, smaller mobile end-points
- Small cells result in higher cell-boundary crossing
 - more signalling overhead
 - performance degradation (more disruption)

Channel Assignment in Cellular System

- Fundamental Problem
 - How to assign channels to requesting call at a BS ?
- Goal: Maximum Spectral Efficiency for a specified grade of service and a given degree of computational complexity
 - probability of new call blocking
 - probability of forced termination
 - link quality
- Maybe a "new" connection, or a connection undergoing "handoff"

Channel Assignment Techniques

- Fixed
 - Basic Fixed
 - Simple borrowing
 - Hybrid borrowing with ordering
- Flexible
 - scheduled
 - predictive
- Dynamic
 - call-by-call optimized

Fixed Channel Assignment

- Basic strategy
 - each cell is statically allocated a subset of channels
 - a requesting call in the cell can only use channel allocated to that cell
 - if no available channel in that cell, the call is blocked
 - MSC only informs new BS about hand-off, & keep track of serving channel

Fixed Channel Assignment

Variation

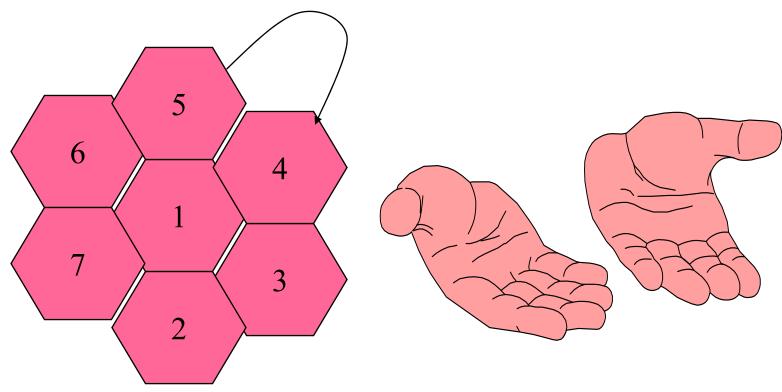

- borrow channel from neighboring BSs if all channels busy at BS under MSC supervision, and only if does not cause interference borrowed channels are "locked"
- hybrid channel assignment
 - two groups of channels: fixed and borrowable
 - ratio determined a priori depending on traffic estimate
- borrow-with-channel-ordering
 - fixed-to-borrowable channel ration varied on changing traffic condition
 - channels are rank ordered

Fixed Channel Assignment

We might borrow from neighboring cells

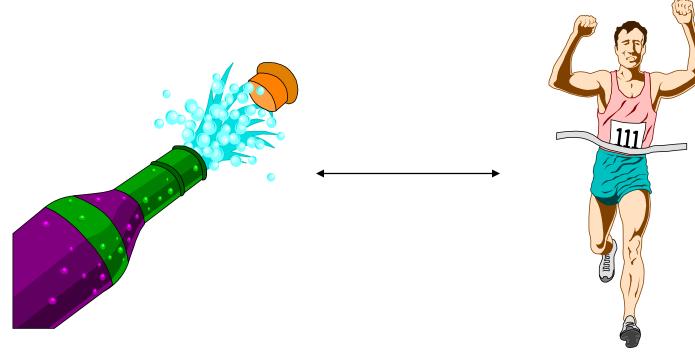

Traffic & Resource

Uniform Distribution

Channel Resource

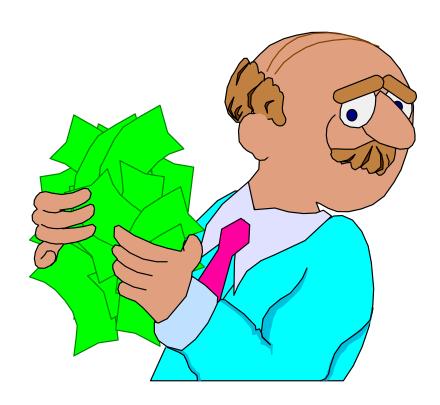

User Demanding

Dynamic & Assignment

Maybe I should assign you based on current condition

Issues to consider

- Selected Cost
- Blocking Probability
- Reuse Distance
- CIR
- QoS (Quality of Service)
 - current value
 - handoff value

Dynamic Channel Assignment (DCA)

- Basic Features
 - channels not allocated to cells permanently
 - MSC allocated channel to a call from the global pool taking into account
 - Advantage: channel assignment may be retained across hand-off
 - Disadvantage: interruptions, deadlocks, instability

Dynamic Channel Assignment

- DCA algorithms differ in distribution of control among BSs and MSC
 - Centralized DCA
 - can do a globally optimized channel assignment and call rearrangement BSs need to communicate with MSC e.g. Maximum Packing
 - Decentralized & Fully Decentralized DCA
 - rely only on local monitoring to make channel assignments
 - require limited local communication among cluster of BSs

Flexible Channel Assignment

- Combine aspects of FCA and DCA
- Each cell is assigned a fixed set of channel
- Plus, a pool of channels is reserved for flexible assignment
 - MSC assigns these channels
- Flexible assignment strategies
 - Scheduled assignment: rely on known foreseeable changes in traffic pattern
 - Predictive assignment: based on measured traffic load at every BS

MSC will pick up one for MH

Here you go!

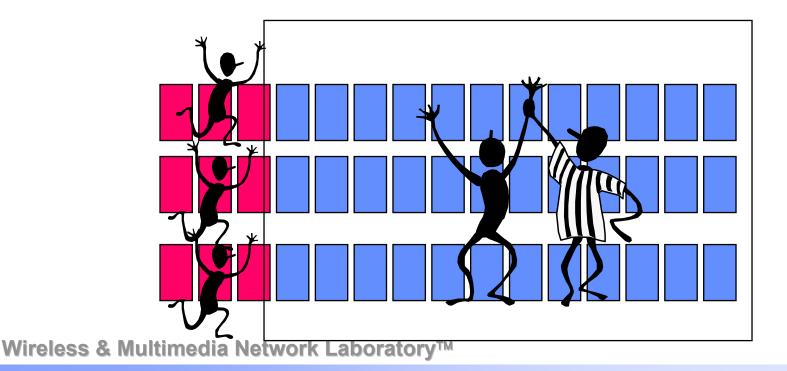

Flexible Channel Assignment

- Assign some of channel for minimum traffic requirement
- Keep all of the others in a service pool

Handoff Handling

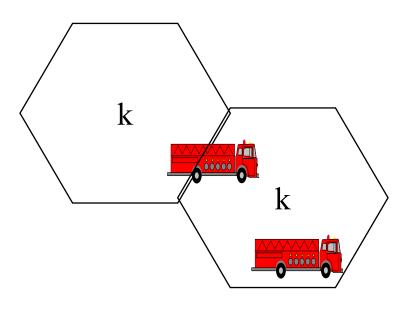

Keep the QoS while the user moves

Handling Handoffs

Handoff

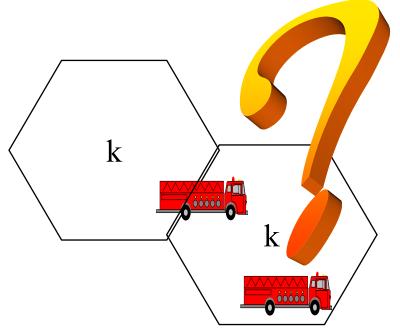

- change the radio channel
 - the same base station
 - the new base station
- due to
 - the radio link degradation
 - channel reorder

What is going to happen?

- The new cell must assign new channel
- We must reserve some hand off channel
- Some connection must be blocked !!

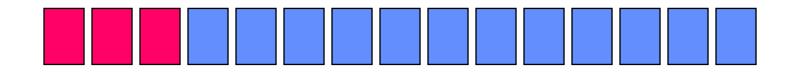

Solutions for handoff

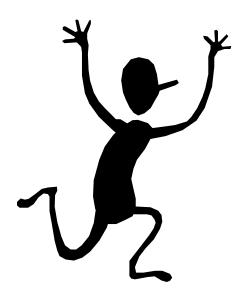

- Handoff Priority
 - guard channel for handoff
 - how much, inefficiency
- Queueing of Handoff request
 - take a seat for future handoff

Guard Channel

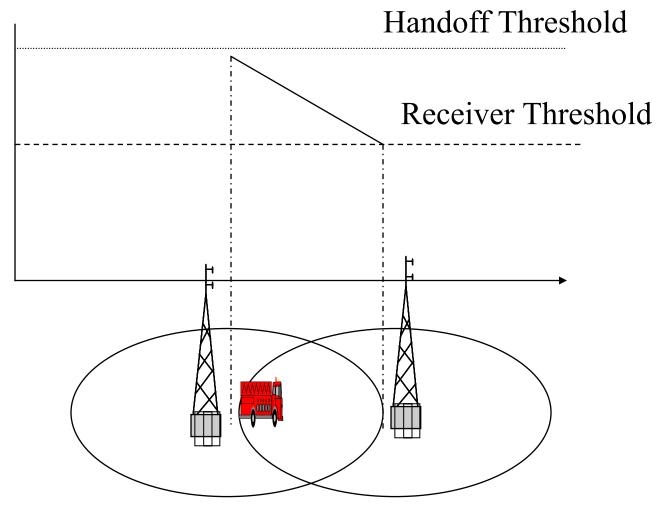

Reserved for Handoff

Thresholds

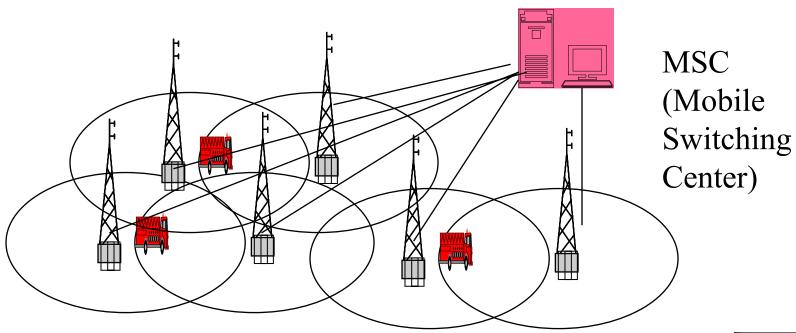

Who is going to take over Handoff

- Yourself (Mobile Users)
- Infrastructure Network
 - Base Station
 - Mobile Switching Center

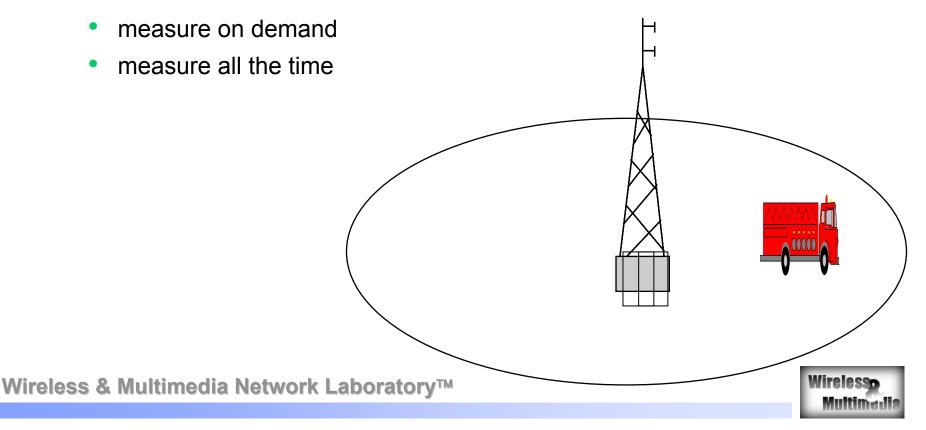

Negotiating Procedure

- Base Station
 - detect the receiving signal from MH
 - send a measurement order
- Mobile Host

Hand off Procedure

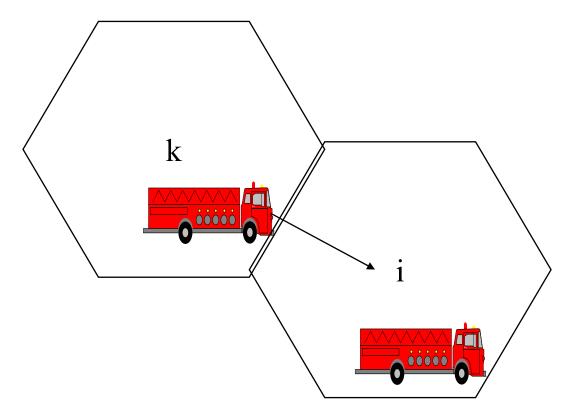

- Decide the New Base Station
 - MSC picks the best for MH
 - MSC picks the candidate MH specify
- New Base Station decides to accept or not?

Call Queueing Scheme

Queue for a channel, handoff threshold, receiver threshold

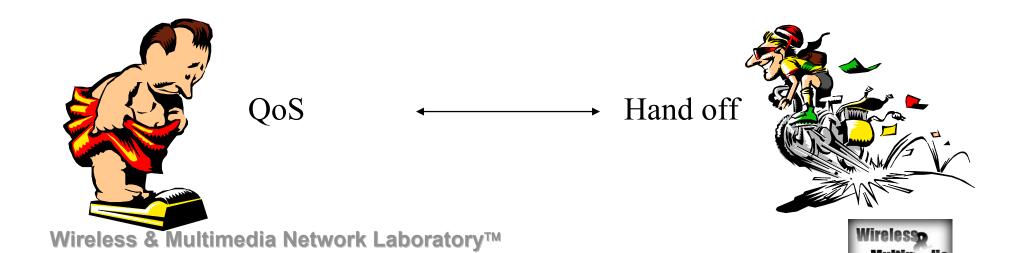

Trends in Hand over Design

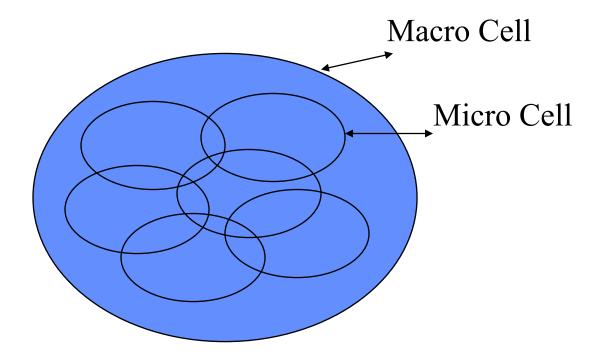

- Hand over and Hand off are the same
- Small cells -> more hand over
 - allocate network resource to reroute the call to the new base station
 - if not quick enough, QoS will drop dramatically

Mobility Solution

- Multi-tiers
 - micro-cell and macro-cell
 - based on the speed
 - different schemes

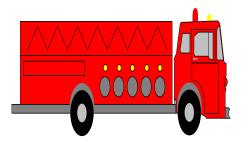

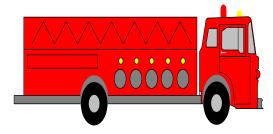

Velocity Estimation

- Doppler Frequency is known -> Estimation of the velocity of the mobile users
- Mobility is estimated from the time spent in a cell

Handoff in Cellular Networks

- Transfer of mobile to a new channel when it crosses cell boundary
 - identify new base station, assign new channel
 - hand-off initiated at a carefully chosen signal level
 - avoid triggering handoff due to momentary fades

Hand-off

- Handoff delay & interruption
 - dropped (or on hold) connection if signal too low before handoff processed
 - performance degradation (disruption) in data stream
- Prioritizing handoffs to reduce probability of dropped call
 - connection dropped if no spare channels in new cell
 - guard channel: subset of channels reserved for handoff requests works well with DCA
 - handoff queuing: time interval between handoff trigger & connection drop cell overlap, speed of mobile

Handoff in Cellular Networks

- Probability of unnecessary Handoffs
- Hard vs. Soft handoff
- Hand off rate
- Handoff also triggers rerouting in the network layer
- Handoff is tightly coupled to DCA, MAC, and Networking Routing

Handoff Strategies (I)

- Network controlled handoff (NCHO)
 - used in first generation analog cellular systems
 - link quality is only monitored by the serving BS and surrounding BS
 - handoff decision is made by the network (typically central agent)
 - handoff delays of several seconds (10) and infrequent link quality updates

Handoff Strategies (II)

- Mobile assisted handoff
 - used in second generation digital cellular system
 - both the mobile and the serving BS measure link quality
 - only mobile measures link quality of alternate BSs
 - mobile periodically sends the link quality measurements to serving BS
 - handoff decision is made by the network
 - handoff delays of few seconds (1-2) and frequent link quality updates

Handoff Strategies (III)

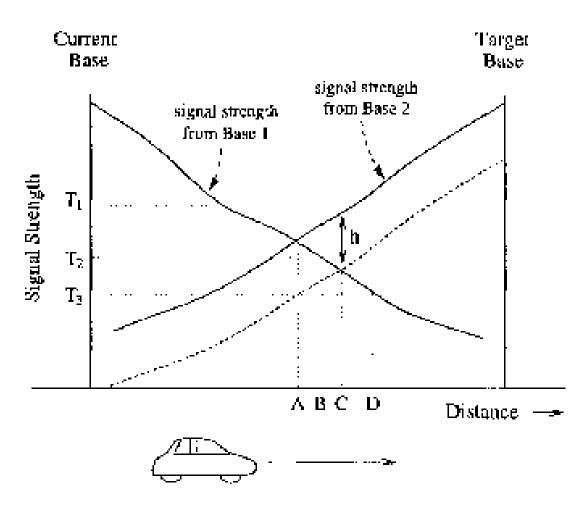

- Mobile controlled hand off
 - used in some new digital cellular systems
 - link quality measurements as in MAHO
 - serving BS relays link quality measurements to mobile
 - handoff decision is made by the mobile
 - handoff delays of about 100 ms

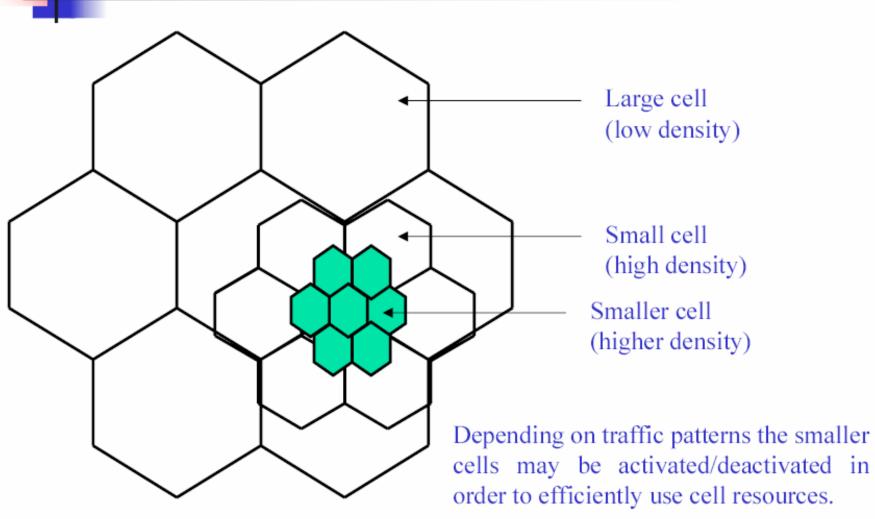

Handoff Scenario

Cell Splitting

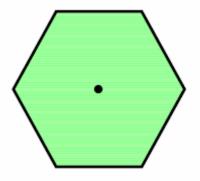

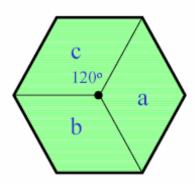

Cell Sectoring by Antenna Design

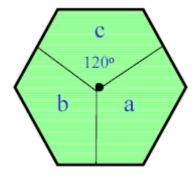

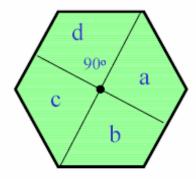

(a). Omni

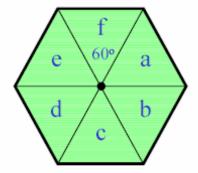

(b). 120° sector

(c). 120° sector (alternate)

(d). 90° sector

(e). 60° sector

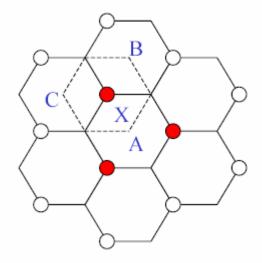

Cell Sectoring by Antenna Design

 Placing directional transmitters at corners where three adjacent cells meet

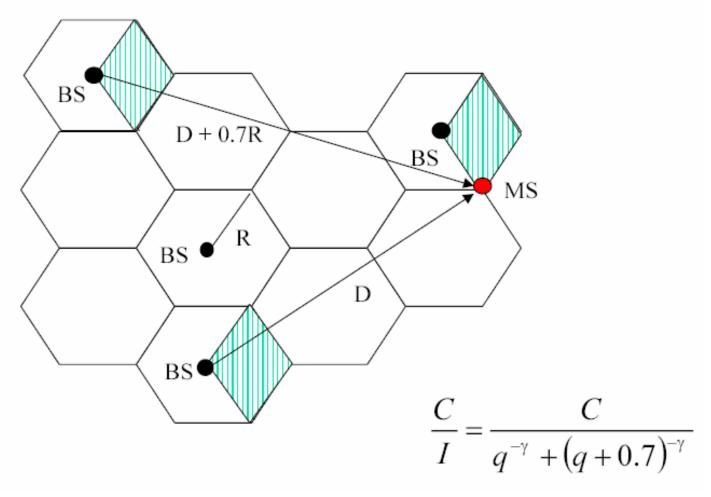

Worst Case for Forward Channel CSE **Interference in Three-sectors**

Worst Case for Forward Channel **Interference in Six-sectors**
