## Wireless Multimedia System

### (Topic 4)

Wireless Link I: Multiple Access Control for  
Multimedia

Dr. Eric Hsiaokuang Wu

*<http://wmlab.csie.ncu.edu.tw/course/wms>*

We provide  
無線網路多媒體實驗室  
Wireless  
Wireless Network & Multimedia Laboratory  
Solution

# Topic III Agenda

## ◆ Wireless Link

- Ad Hoc MAC
  - ◆ Bluetooth
  - ◆ 802.11
- Cellular MAC
  - ◆ GPRS

# Demand for Medium Access Control

Voice Network  
Data Network

Multimedia  
Network

Soft Resource  
Flexible QoS

# Can we distinguish the traffic and offer different QoS?

Data: WWW, Email  
Voice: telephone  
Video: streaming

Calendar  
Earphone  
VideoClip

# Possible Solutions

GPRS (GSM)

802.11

Bluetooth

# Basic Questions

- ◆ How to deliver my stuff safely?

# Three Concerns

Control Resource

Acquiring Channel

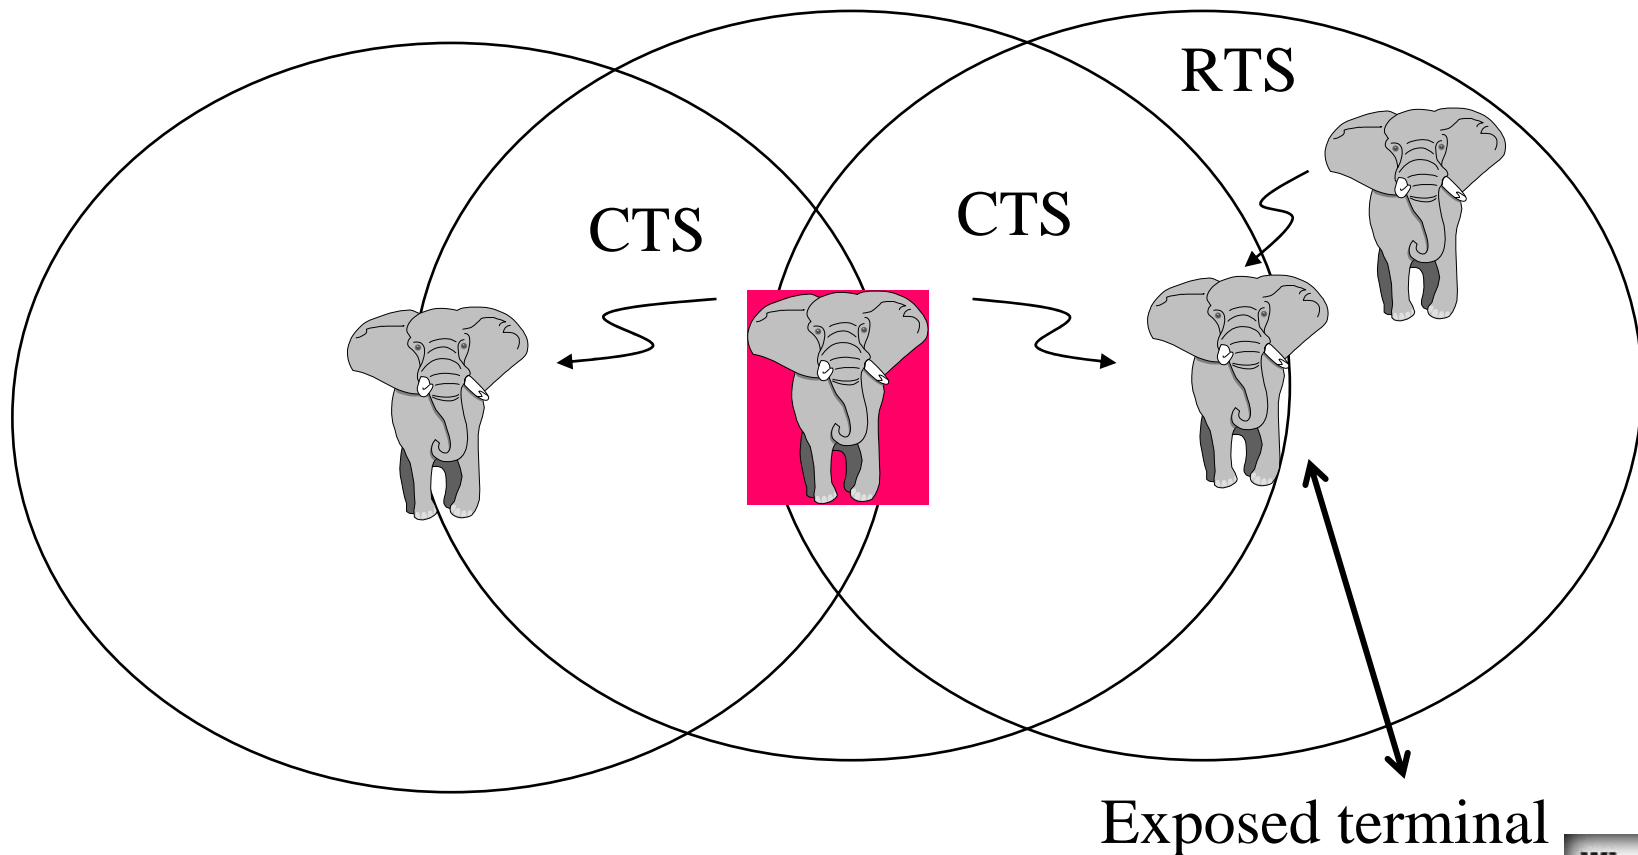

Collision  
Free

# CTS might be collided

- ◆ Whether CTS could be alive?

# Basic Issues for Channel Access

## ◆ Channel Acquisitions?

- Aloha (go ahead)
- CSMA (signal sensing)
- 802.11 (through RTS/CTS dialog, CW for backoff procedure  $T_{\text{backoff}} = \text{Rand}(0, \text{CW}) * T_{\text{slot}}$ )
- Collision free (through effective CTS)
- MACAW (through RTS/CTS/DS/DATA/ACK)
- PCMA (through power control and busy tone)

## ◆ Collision Channel Transmissions

- Centralized Control or Distributed Control
- QoS
- Cycle Time.

## ◆ Spread Spectrum

- Interference suppression

# Reading list for This Lecture

## ◆ Required Reading:

(Haartsen2000) Jaap C. Haartsen, "The Bluetooth Radio System", IEEE Personal Communications, February 2000

(Barry2001) Michael Barry, Andrew T. Campbell, Andras Veres, "Distributed Control Algorithms for Service Differentiation in Wireless Packet Networks", IEEE Infocom 2001

(Cai1997) Jian Cai and David J. Goodman, "General Packet Radio Service in GSM", IEEE Communication Magazine, Oct 1997

# History of Mobile Ad Hoc Network (MANET)

CSMA

1994 GloMo  
802.11

# Commercial Applications of Ad hoc Network

- ◆ Conferencing
- ◆ Home Networking
- ◆ Emergency Services
- ◆ Personal Area Networks and Bluetooth
- ◆ Embedded Computing Applications
- ◆ Sensor Dust
- ◆ Automotive/PC Interaction
- ◆ Other Envisioned Applications

# Technical and Market Factors for Ad hoc Networks

- ◆ Scalability
- ◆ Power Budget versus Latency
- ◆ Protocol Deployment and Incompatible Standards
- ◆ Wireless Data Rates
- ◆ User Education and Acculturation
- ◆ Additional Security Exposure
- ◆ Spotty Coverage

# Bluetooth

supported by Ericsson, Nokia, Ibm, Toshiba, Intel..etc

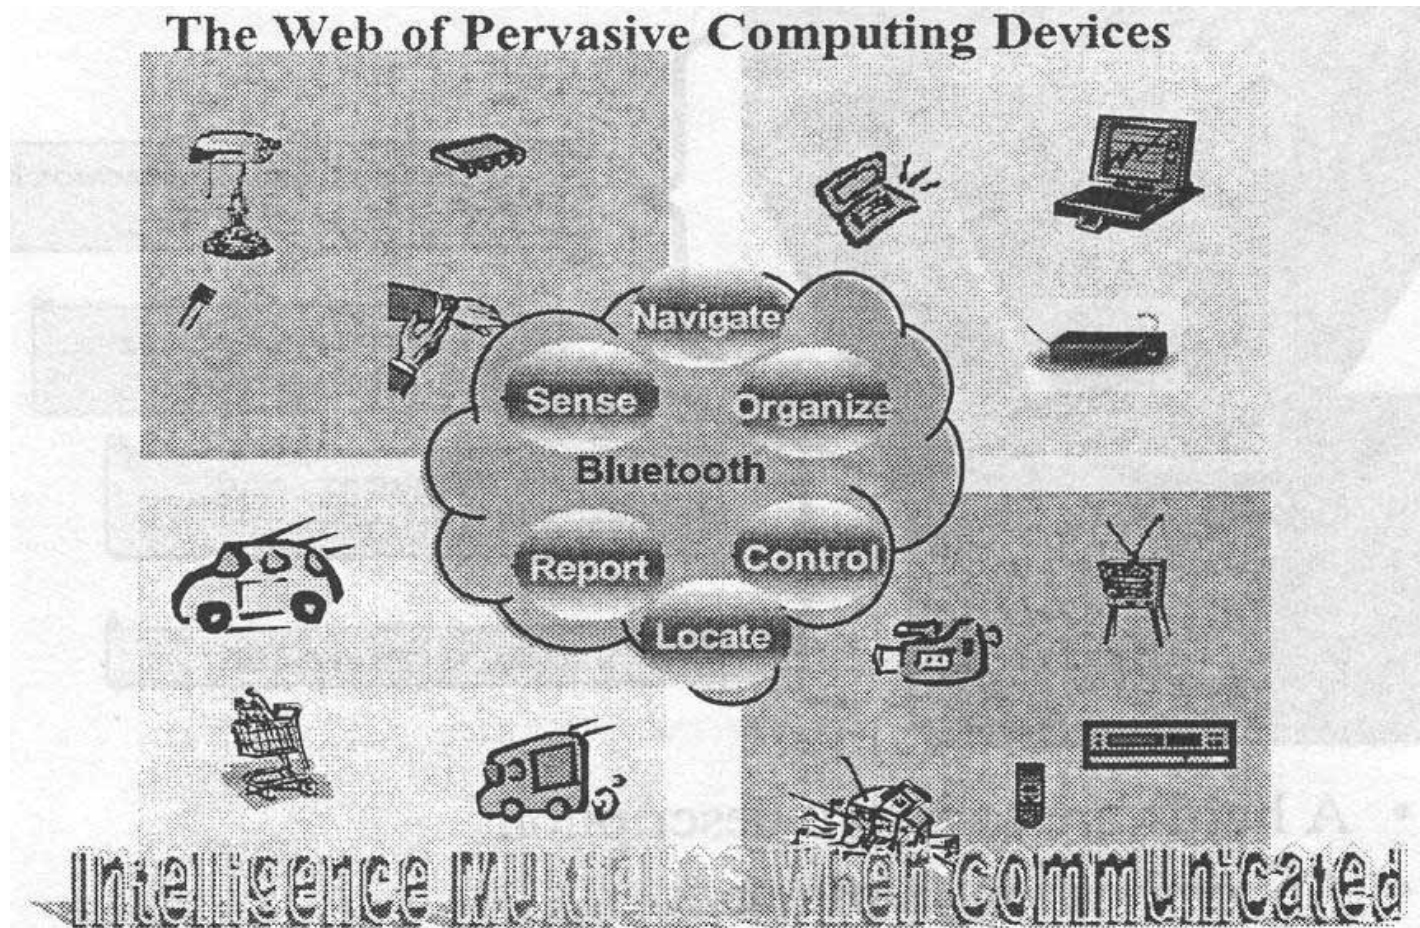

Personal Area Network

Embedded Computing Applications

Ubiquitous Computing

# Smart Spaces and Devices

# Spread Spectrum vs. Narrow Band

## ◆ Spread Spectrum Signal Characteristics

- ◆ The bandwidth of the transmitted signal is much greater than the original message bandwidth
- ◆ The bandwidth of the transmitted signal is determined by a spreading function (code), independent of the message, and known only to transmitter and receiver

## Direct Sequence Spread Spectrum

To transmit a 0 the station use a unique “chip sequence”:

To transmit a 1 the station use the one's complement of its chip sequence:

Therefore if data is 1010 it will transmit:

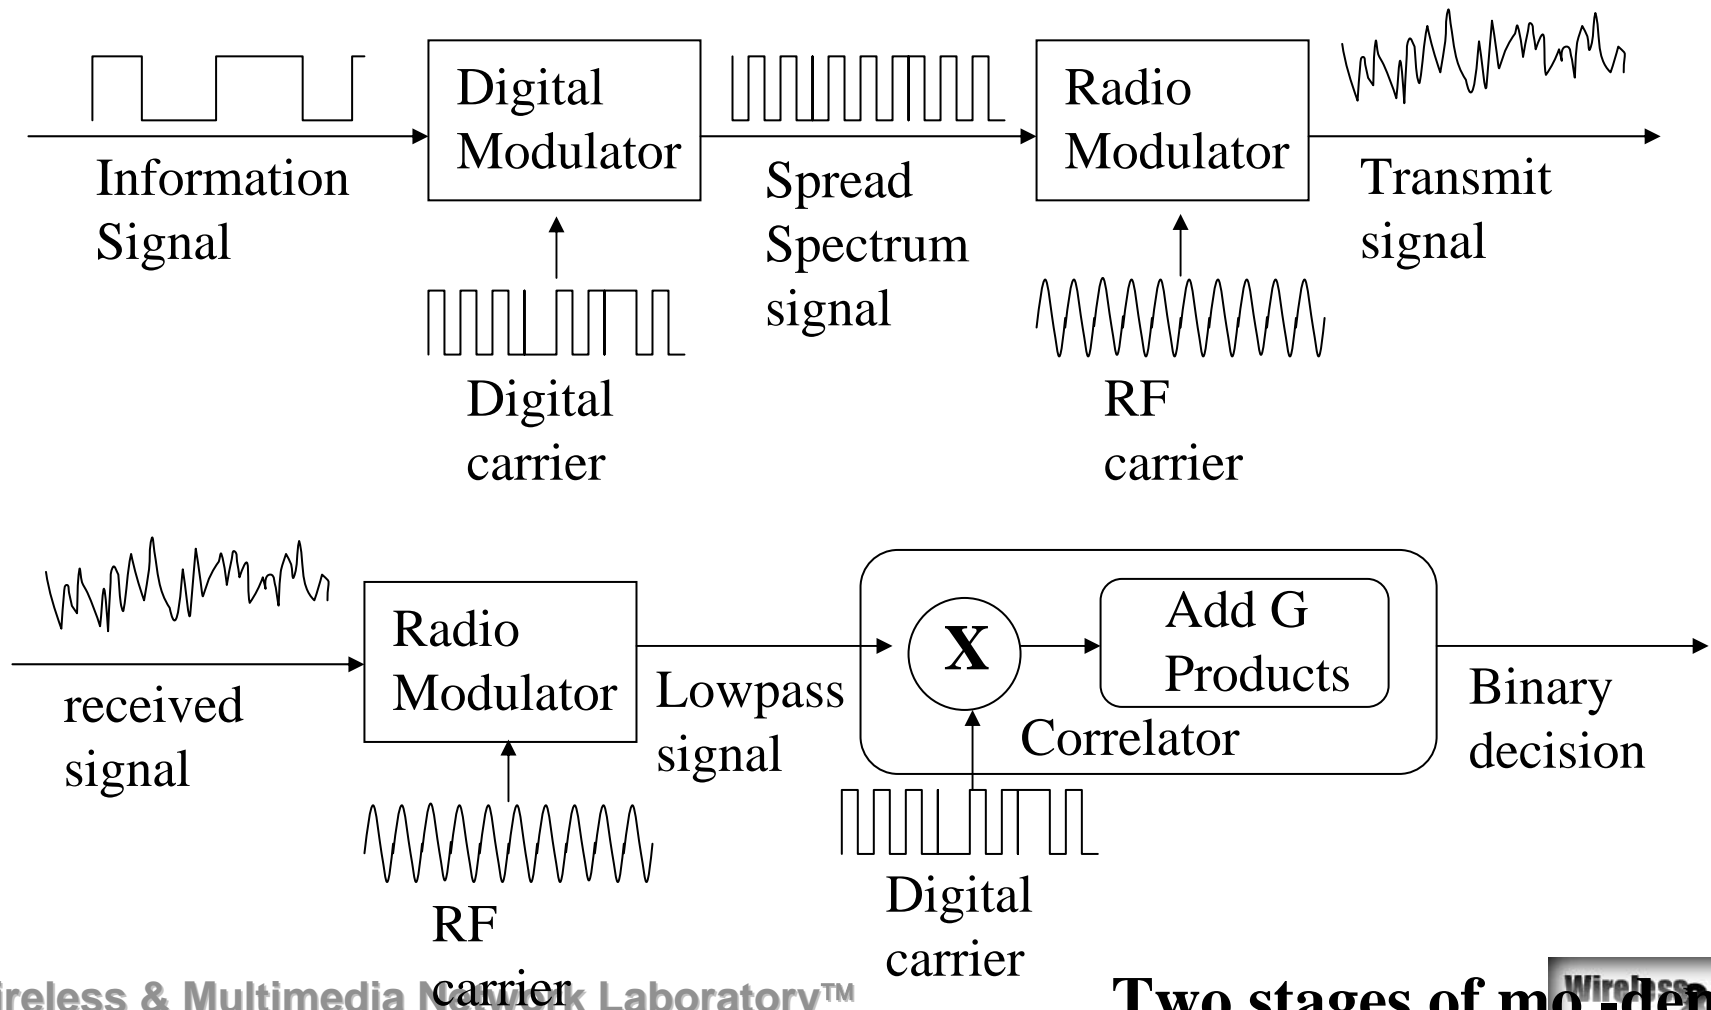

## Frequency Hopping Spread Spectrum

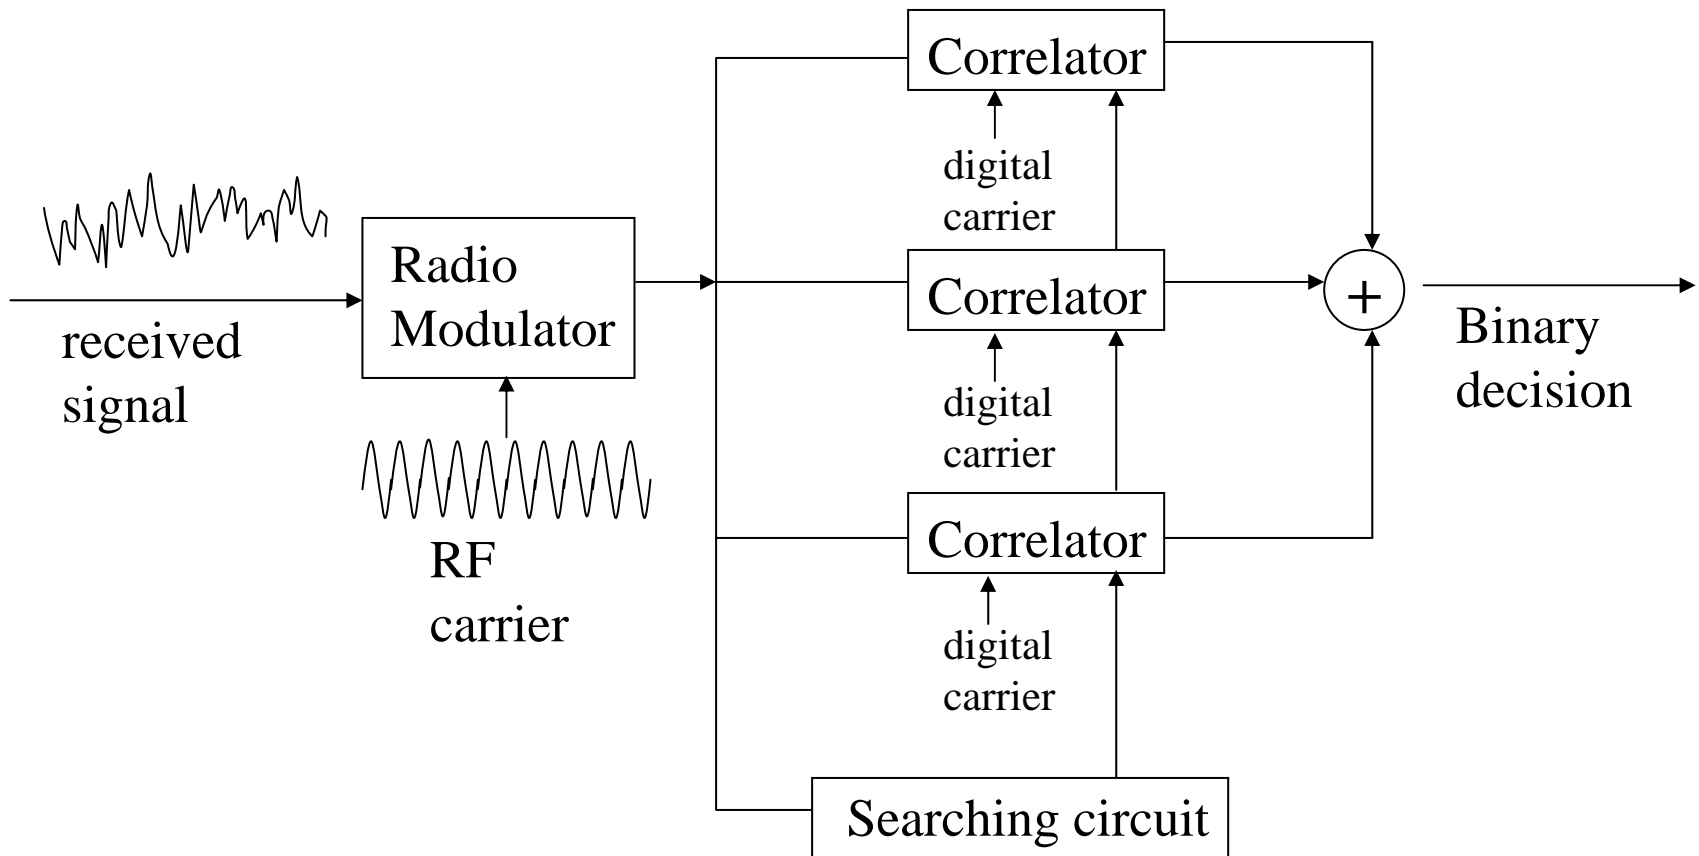

- ◆ Transmitted signal is spread over a wide range of frequencies. (i.e. 2.400-2.485 GHz)
- ◆ Transmission usually hop 35 times per second.

# Rake Receiver

# Rake Receiver ( cont. )

# The Industrial, Scientific, and Medical frequency bands(ISM)

The spectrum is not coordinated by operator, open to the public

## ISM Bands in Taiwan

# Typical Bluetooth Service

# Basic Questions? Find your partners?

**Connection Establishments**  
**Scan, Page and Inquiry**

# Step1 Inquiry

# Centrally polling control

# Multi Slot Packets

# Physical Link Types

- ◆ **Synchronous Connection Oriented (SCO) Link**
  - slot reservation at intervals
- ◆ **Asynchronous Connection-less (ACL) Link**
  - Polling access method

# Overview of Bluetooth

- ◆ **Short range radio research**
  - Providing Ad hoc networking between cellular phones, notebook computer, and PDA, etc.
  
- ◆ **Bluetooth answers the need for short range wireless connectivity within three areas:**
  - Data and Voice access points
  - Cable replacement
  - Ad hoc networking

# Overview of Bluetooth

- ◆ **Bluetooth radio**
  - operates in a globally available 2.4 GHz ISM band, ensuring communication compatibility worldwide.
  - Gross data rate is 1Mb/s.
- ◆ **Bluetooth baseband – mac layer of Bluetooth**
  - fast acknowledgement ( 1-bit piggyback ack)
  - frequency hopping scheme
  - A Time-Division Duplex scheme is used for full-duplex transmission
  - Transmissions centrally controlled by the master with polling scheme

# Overview of Bluetooth

## ◆ Bluetooth data rate

- Voice channel supports 64 kb/s synchronous (voice) link
- asynchronous channel can support an asymmetric link of maximally 721 kb/s
- maximally 432.6 kb/s for symmetric link

## ◆ Bluetooth network

- A piconet contains a master and up to 7 slaves
- Several piconets can be linked together, forming a scatternet
- Each piconet is identified by a deferent frequency hopping sequence

# Inquiry & Inquiry Scan

## Step2 Page

# CREATING A PICONET

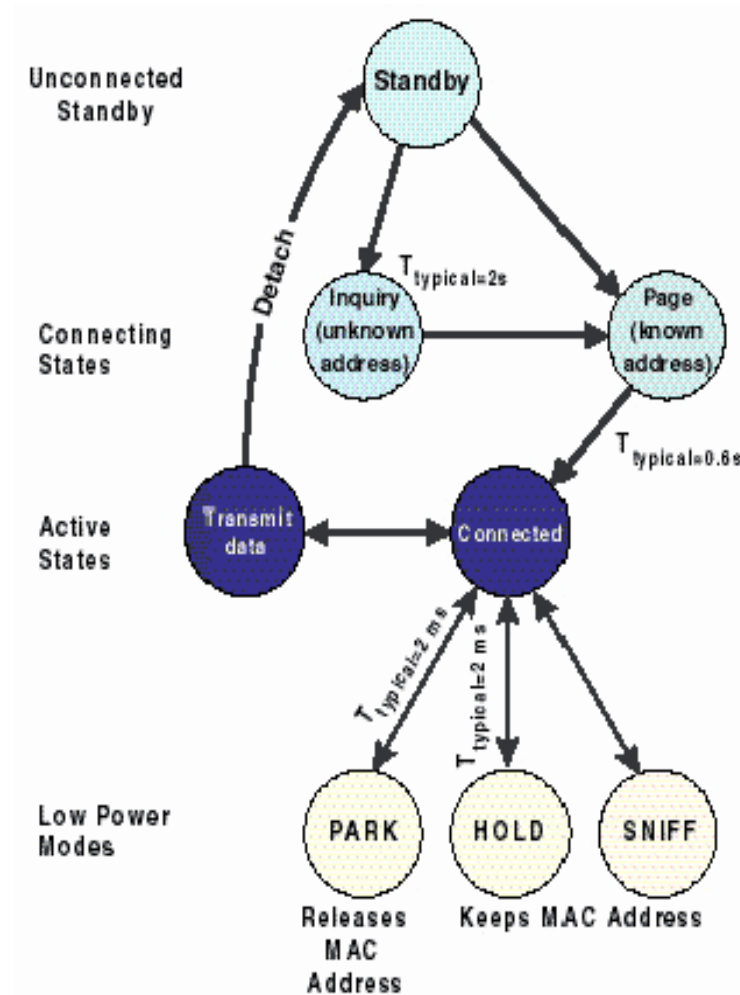

# The Bluetooth asymmetric point to point connection establishment protocol

# Piconet & Scatternet

# State diagram of Bluetooth

# Protocol Stack of Bluetooth

# **Scatternet establishment**

## ◆ **Start up procedure**

- Enter Inquiry and Inquiry scan state in term for a period of time
- Discovering neighbors
- Arrange neighbors table(self id included) with device id by increasing order, therefore, each unit get a sequence number, we call this number as pseudo candidate sequence number, because the lack of communication channel between units; self device id should be at 8<sup>th</sup> notch or before 8<sup>th</sup> notch
- Enter paging frame

# Paging frame

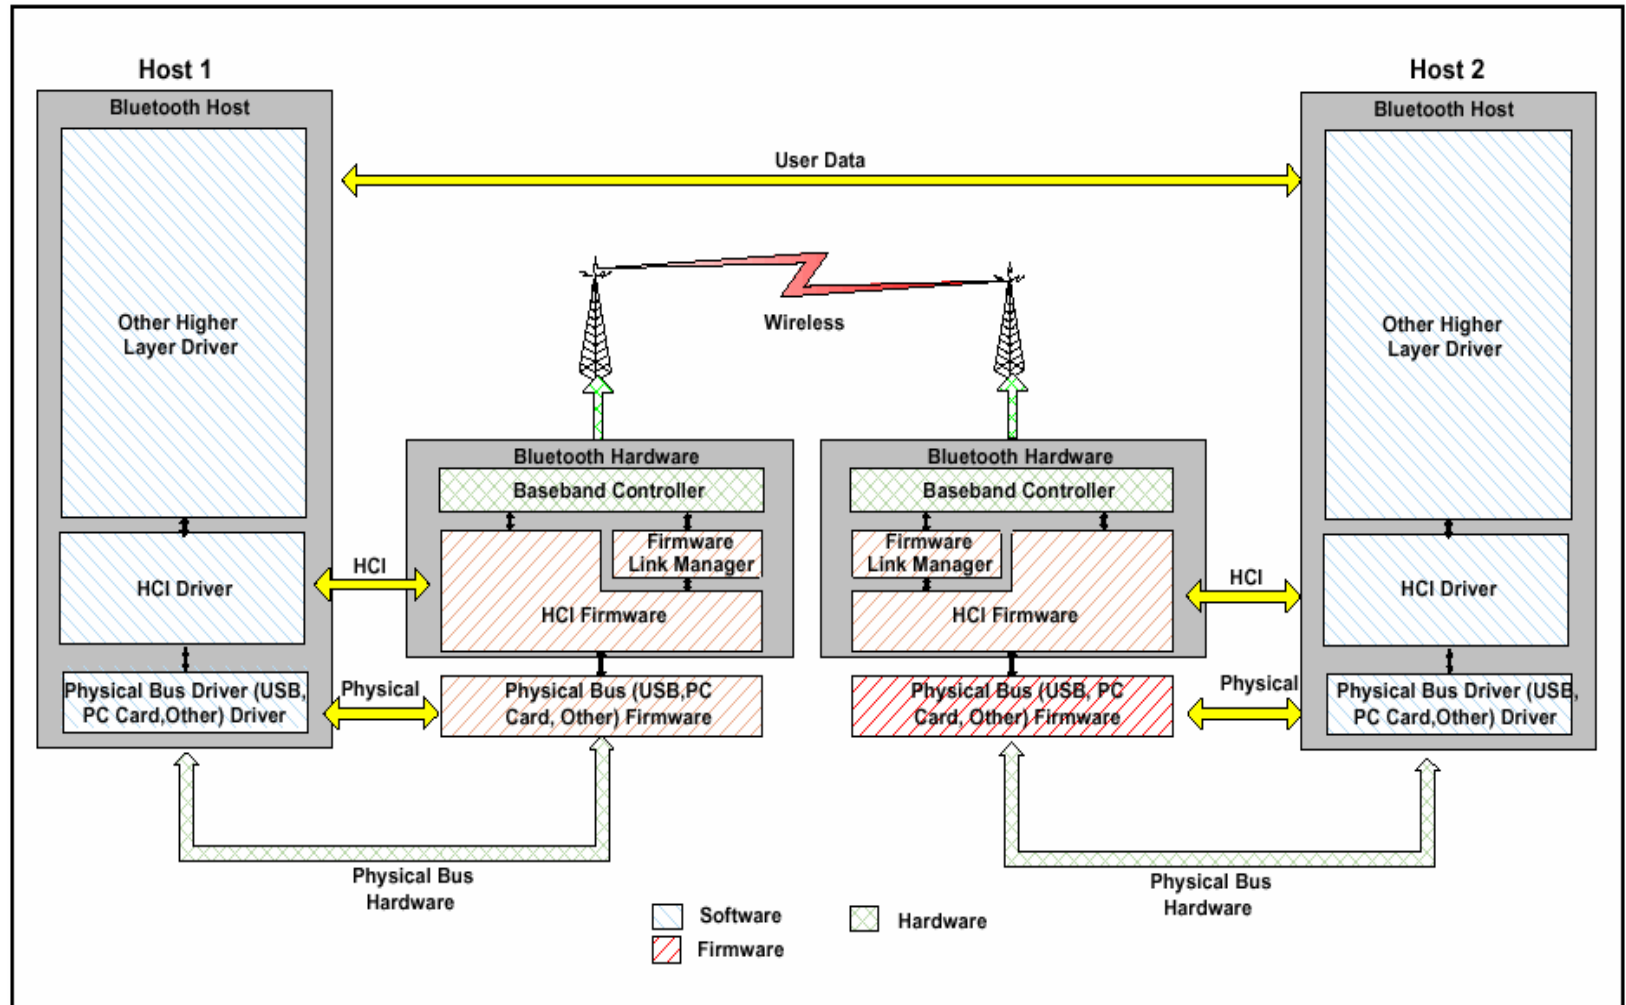

P1	P2	P3	P4	P5	P6	P7	P8
----	----	----	----	----	----	----	----

- ◆ A paging frame contains 8 paging slots
- ◆ An unit enter the paging frame will waiting for a number of slots and stay in page scan state, say if one's pseudo candidate sequence number is 5, then it should stay in page scan state for 4 paging slots long
- ◆ During the waiting time, the unit should be ready to participate in any piconet, once it becomes a member of a piconet, the start up procedure ended, and any unit continuously enter page scan state periodically
- ◆ If the unit does not participate in any piconet after the waiting time, it start to page and become a master itself, it will page all the items in the neighbors table

# Benefit of the procedure

- ◆ Each unit will participate in at least one piconet
- ◆ By waiting for a period of time, less piconets are established, this will reduce the hopping overload
- ◆ Because any unit will at latest establish a new piconet at the end of paging frame, the time complex of the scatternet establishment will be constant
- ◆ Because after the start up procedure, each unit will enter page scan state periodically, so, overlapping between piconets are built during the procedure
- ◆ A new start up unit will easily participate in the scatternet with the same start up procedure

# Routing over Baseband

# Packet field

- ◆ Add a field in the packet, the field indicate the final destination
- ◆ Routing table is kept in HCI firmware, so the packet could be rescheduled right away according the “Destination Device Id” field, no higher layer protocol is needed
- ◆ HCI firmware adjust the “AM\_ADDR” in the HEADER and replace “ACCESS CODE” if needed, then switch to the specified piconet or just transport the packet to the specified slave

# Benefit and disadvantage

- ◆ SAR procedure are avoided during intermediate hopping, this is beneficial to the device with low computing capability
- ◆ Rescheduling of the packet is direct and fast
- ◆ Any Bluetooth device could be the intermediate ones no matter with what high layer protocols it supports
- ◆ Each MAC layer packet has 48 bits overhead

# Routing over L2CAP layer

# Packet field

- ◆ L2CAP follows a communication based on channels
- ◆ The channel ID identifies the destination channel endpoint of the packet
- ◆ To achieve routing, a field “Destination Device ID” is added into the L2CAP layer payload
- ◆ After the whole PDU is received, the L2CAP layer could decide the next hop according to the routing table and the “Destination Device”, and then make a new channel to the next hop, if the channel exists, it just replaces the “Channel ID”, and then retransmits the PDU through the channel

# Benefit and disadvantage

- ◆ Routing over L2CAP layer is based on channel transmission, if the channel to the desired existed, than a connect establishment is not needed, this reduce the overhead
- ◆ A PDU could contain up to 64K bytes data, and only 48 bit overhead needed, its consuming is far less than the routing over baseband method
- ◆ Disadvantage of this method is the additional work of SAR, but it is not serious if the device computing capability is good
- ◆ The significant disadvantage is that the synchronous data not transmitted through L2CAP, so these data could not be routing by this method

# Unit discovering

- ◆ The discussed routing method above is based on table driven, that is every unit will learn the routing information of the units in the scatternet, therefore, the unit discovering could be expanded to the scope of a scatternt

# Work in the future

- ◆ Multicast performance
- ◆ Support of QoS through scheduling and priority
- ◆ IP addressing
- ◆ Mobile IP and scatternet interworking

# Multihop for bluetooth

- ◆ **Broadcast enabled over Bluetooth scatternet**
  - Mac address identification
  - Broadcast address identification
- ◆ **IP transparent**
  - Data forwarding protocol below IP layer
- ◆ **Multi-hop multimedia transmission support**
  - Pre-probe polling method
  - Virtual Link Path(VLP) reservation protocol

# System Description

- ◆ **Wireless Personal Area Network (WPAN)**
- ◆ **LAN-link environment**
  - Several WPANs may form an Ad hoc network via Bluetooth radio
- ◆ **Multimedia transmission between WPANs**

# Network scenario

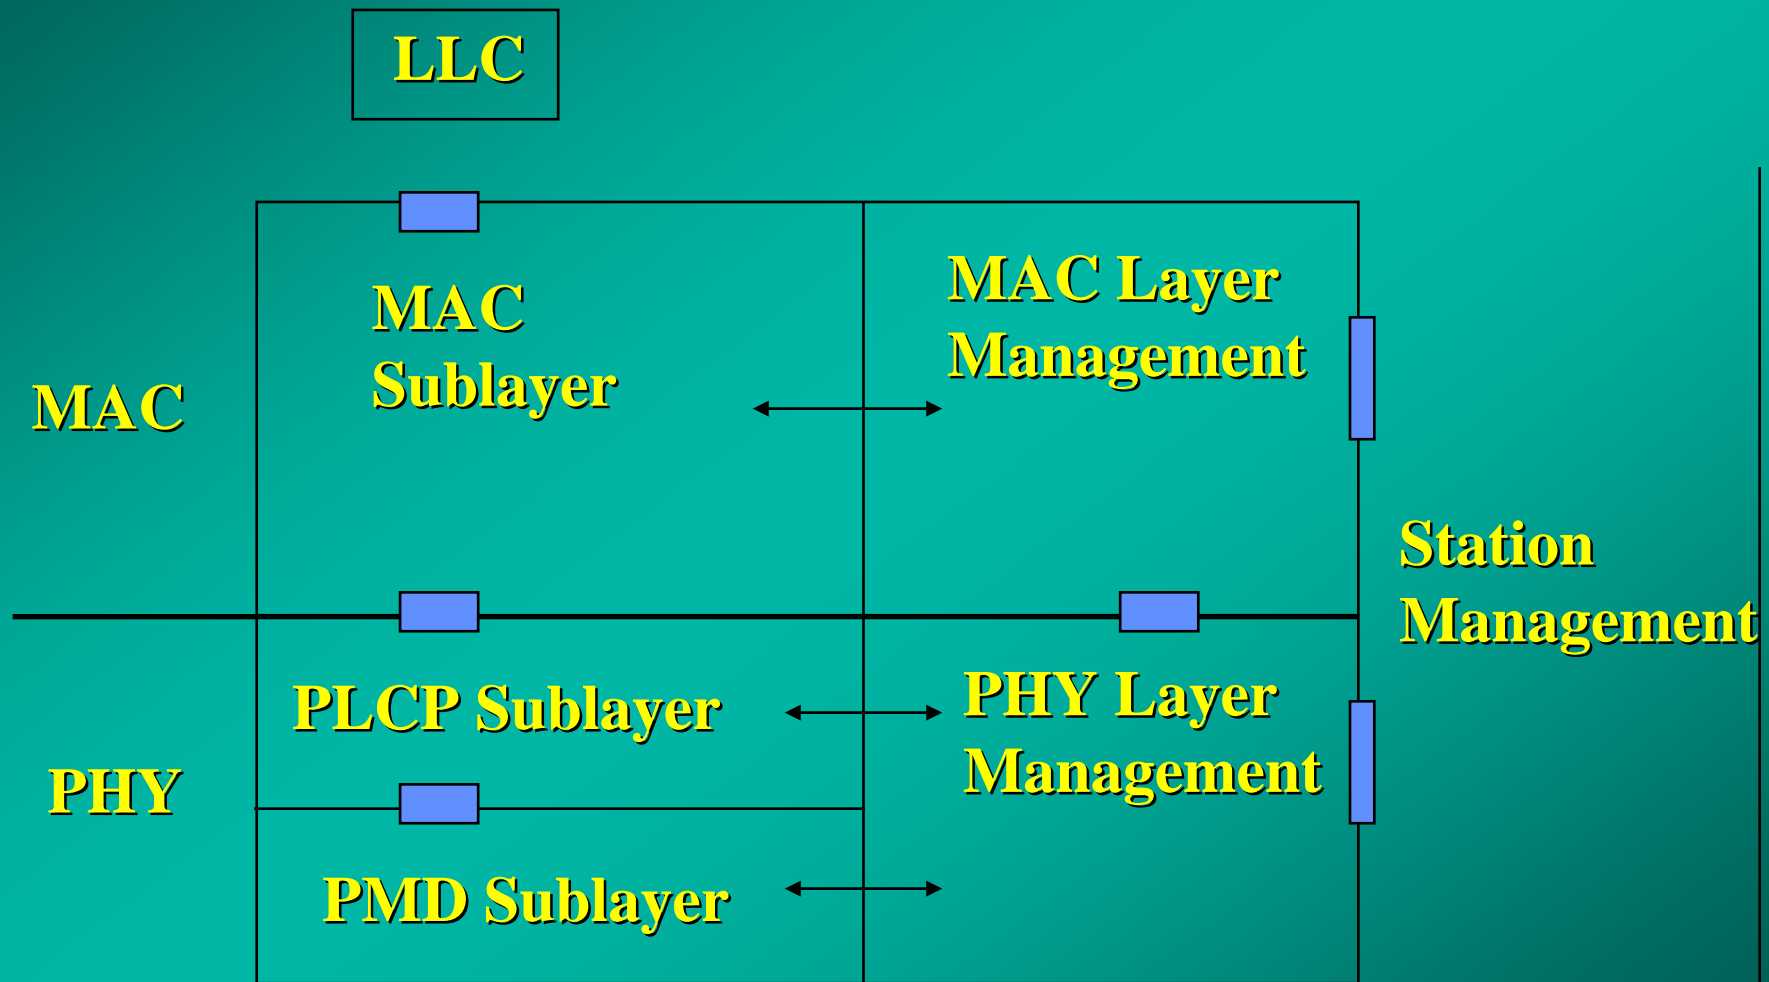

# Research Topic for Bluetooth

- ◆ Multicasting
- ◆ Scheduling

- ◆ Integration with Cellular Systems

# IEEE 802.11

# IEEE 802.11 Protocol Entities

# IEEE 802.11 Protocol Architecture

- ◆ MAC Entity
  - **basic access mechanism**
  - **fragmentation**
  - **encryption ( RC4 PRNG Algo. 40 bit secret key )**
- ◆ MAC Layer Management Entity
  - **synchronization**
  - **power management**
  - **roaming**
  - **MAC MIB**
- ◆ Physical Layer Convergence Protocol (PLCP)
  - **PHY-specific, supports common PHY SAP**
  - **provides Clear Channel Assessment signal (carrier sense)**

# IEEE 802.11 Protocol Architecture

- ◆ Physical Medium Dependent Sublayer (PMD)
  - **modulation and encoding**
  
- ◆ PHY Layer Management
  - **channel tuning**
  - **PHY MIB**
  
- ◆ Station Management
  - **interacts with both MAC Management and PHY Management**

## 名詞解釋

- ◆ **Basic Service Set ( BSS )** - is the fundamental building block of the IEEE 802.11 architecture. A BSS is defined as a group of stations that are under the direct control of a single coordination function , i.e. , a DCF or PCF .

## 名詞解釋

- ◆ **Coordination Function ( CF )** - That logical function which determines when a station operating within a Basic Service Set transmits and receives via the wireless medium.

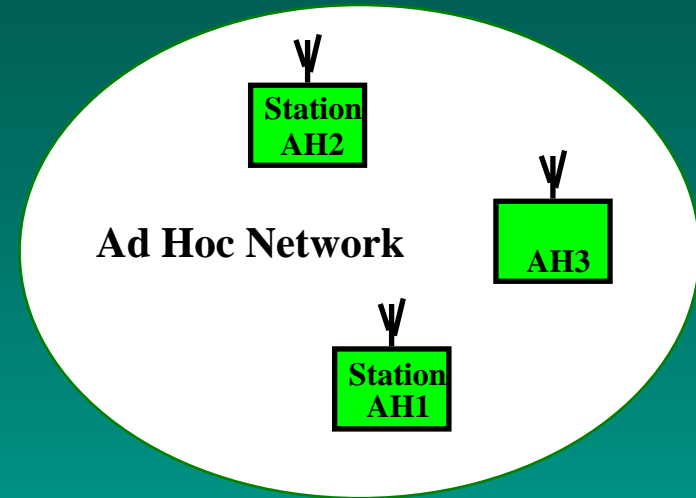

## IEEE 802.11 Wireless LAN Architecture

- ◆ **Ad Hoc Network ( Independent Basic Service Set Network : IBSS Network )**
- ◆ **Infrastructure Network**

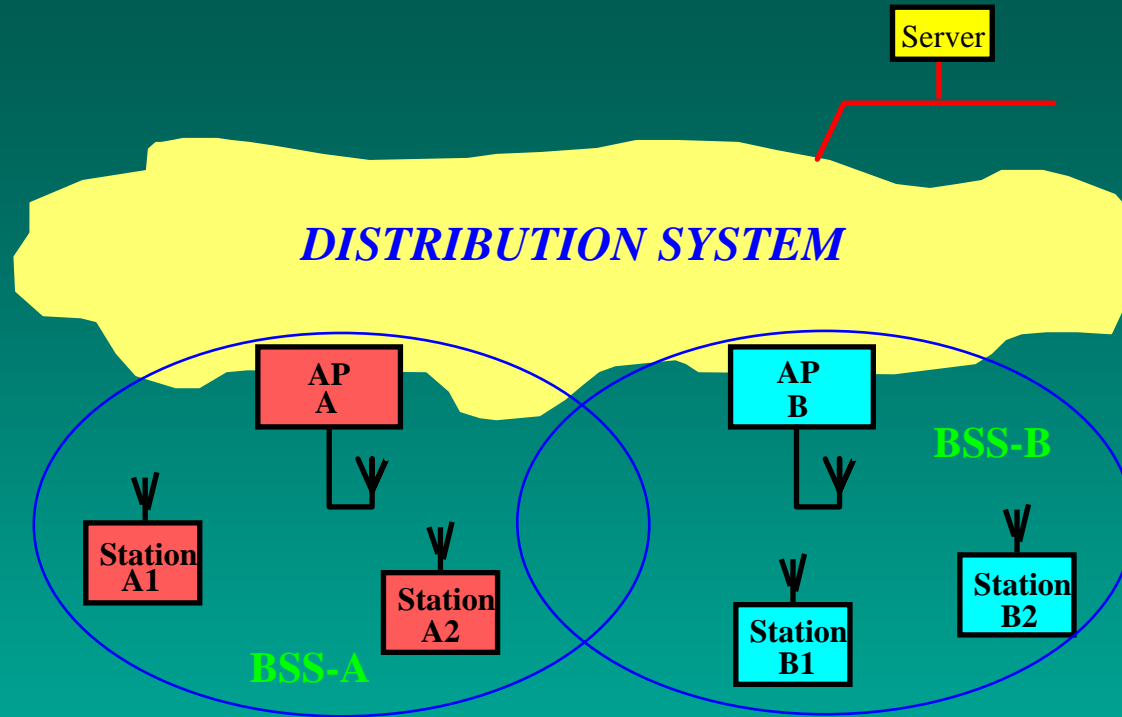

# IEEE 802.11 Configurations - Independent

## ◆ Independent

- one Basic Service Set - BSS
- Ad Hoc network
- direct communication
- limited coverage area

# IEEE 802.11 Configurations - Infrastructure

- ◆ Infrastructure
  - **Access Points and stations**
- ◆ Distribution System interconnects Multiple Cells via Access Points to form a single Network.
  - **extends wireless coverage area**

# Distribution System

Used to interconnect wireless cells

**multiple BSSs connected together form an ESS, Extended Service Set**

Not part of 802.11 standard

**could be bridged IEEE LANs, wireless, other networks**

**Distribution System Services are defined**

# Access Point

Stations select an AP and Associate with it

Support roaming

Provide other functions

**time synchronization ( beaconing )**

**power management support**

**point coordination function**

Traffic typically (but not always) flows through AP

**direct communication possible**

# Services Provided by MAC

- ◆ **Distribution System Service** - Divided into six kinds of service. Let data be received or sent between station and station.
- ◆ **Station Service** - Divided into three kinds of service. Controlling access and privacy of IEEE 802.11 Wireless Network.

# Distribution System Services

- ◆ **Distribution** - Send data , which is in distribution system , to correct address
- ◆ **Integration** - Exchange data between Distribution System and existent wired network

# Distribution System Services

## ◆ Association

Mobility of Station

- **No-Transition**
  - ◆ **Static**
  - ◆ **Local Movement**
- **BSS-Transition**
- **ESS-Transition**

Stations must establish connection with AP before sending data to it. This action is provided by Association service.

# Distribution System Services

## ◆ Reassociation

Requested by station

- **Move a current association from one AP to another**
- **Change connection type**

# Distribution System Services

## ◆ Deassociation

Requested by station or AP

- **Stations leave the wireless network**
- **AP close or can't provide some services**

Station or AP can't refuse Deassociation sent by the other

# Distribution System Services

- ◆ MSDU delivery

Frames received or sent between stations and stations is provided by this service

- ◆ MSDU - MAC Service Data Unit

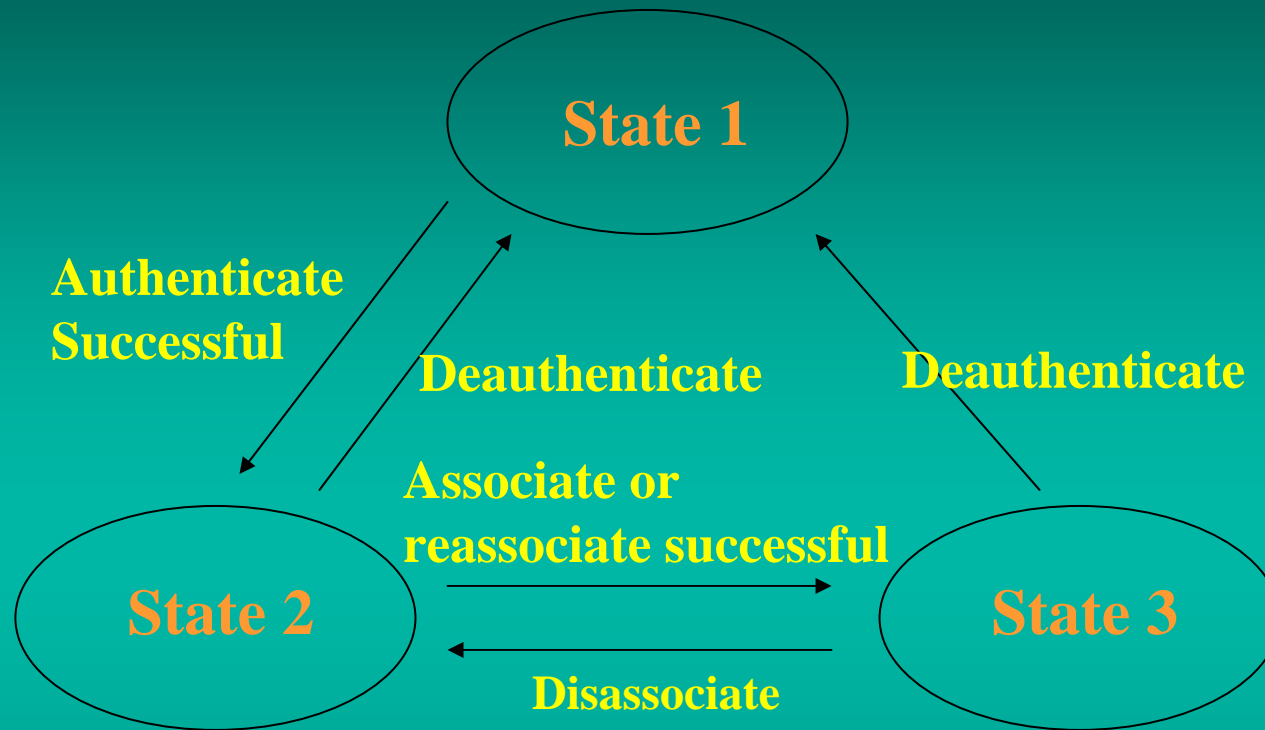

# Station Service

- ◆ Authentication
  - **Open System**
  - **Shared Key**
- ◆ Deauthentication - When Authentication is cancelled , Association will be cancelled at the same time
- ◆ Privacy - The 802.11 embeds the WEP ( Wired Equivalent Privacy ) mechanism within the MAC that covers station-to-station transmission

# Relationships between Services

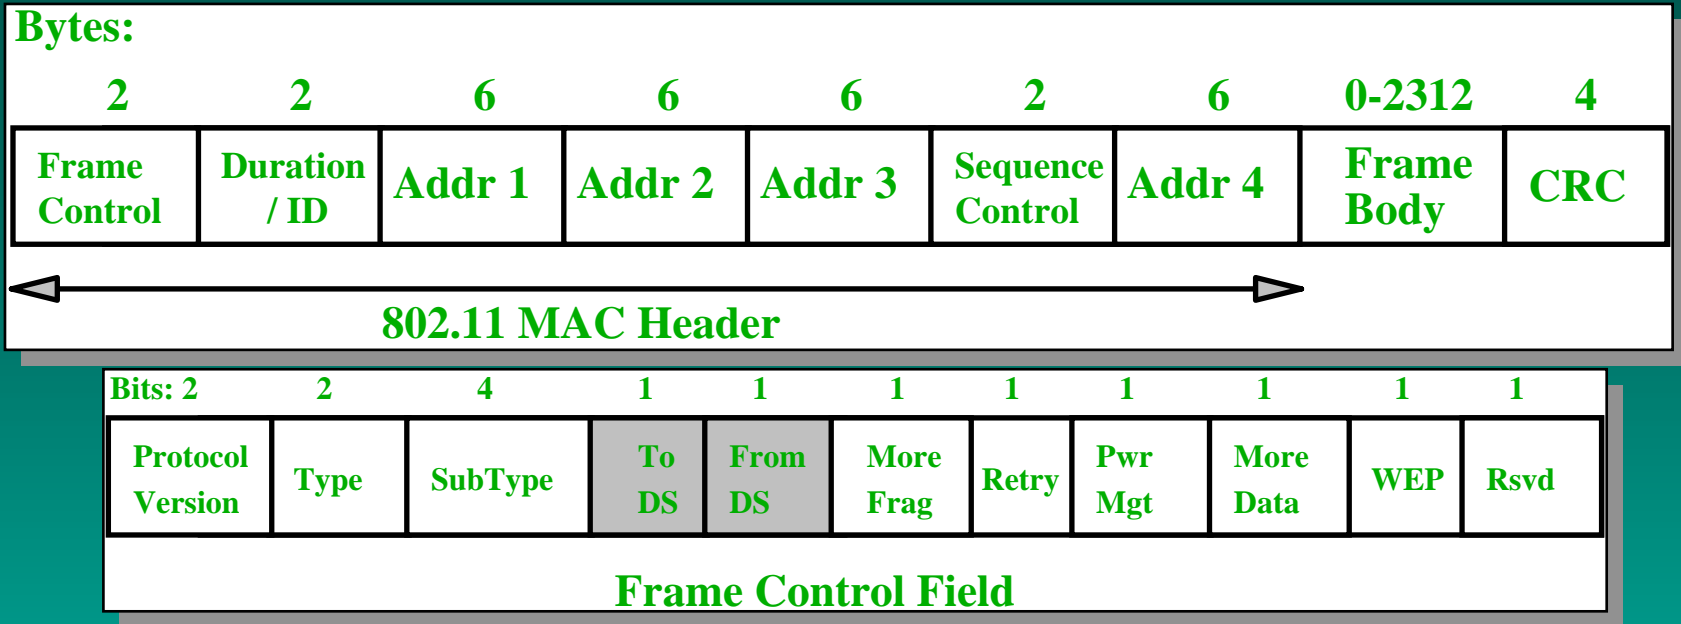

There two state variable ( Authentication , Association ) create three station states :

- ◆ Initial State , Unauthenticated , Unassociated
- ◆ Authenticated , not Associated
- ◆ Authenticated and Associated

## Relations Between State Variables and Services

# MAC Frame Formats

- ◆ MAC Header format differs per Type:
  - **Control Frames (several fields are omitted)**
  - **Management Frames**
  - **Data Frames**
- ◆ Includes Sequence Control Field for filtering of duplicate caused by ACK mechanism.

## Address Field Description

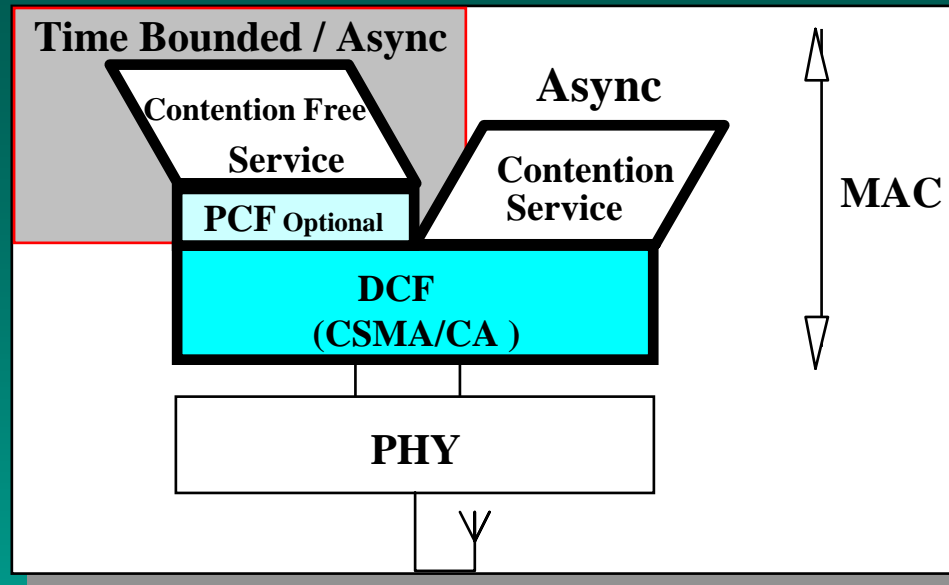

To DS	From DS	Address 1	Address 2	Address 3	Address 4
0	0	DA	SA	BSSID	N/A
0	1	DA	BSSID	SA	N/A
1	0	BSSID	SA	DA	N/A
1	1	RA	TA	DA	SA

- ◆ Addr 1 = All stations filter on this address.
- ◆ Addr 2 = Transmitter Address (TA)
  - **Identifies transmitter to address the ACK frame to.**
- ◆ Addr 3 = Dependent on *To* and *From DS* bits.
- ◆ Addr 4 = Only needed to identify the original source of WDS (*Wireless Distribution System*) frames.

# CSMA/CA Protocol

- ◆ IEEE 802.11 use CSMA/CA protocol
- ◆ IEEE 802.11 provide two categories of basic access method
  - **Distributed Coordination Function ( DCF )**
  - **Pointed Coordination Function ( PCF )**
    - ◆ **Provide Time Bounded Service**

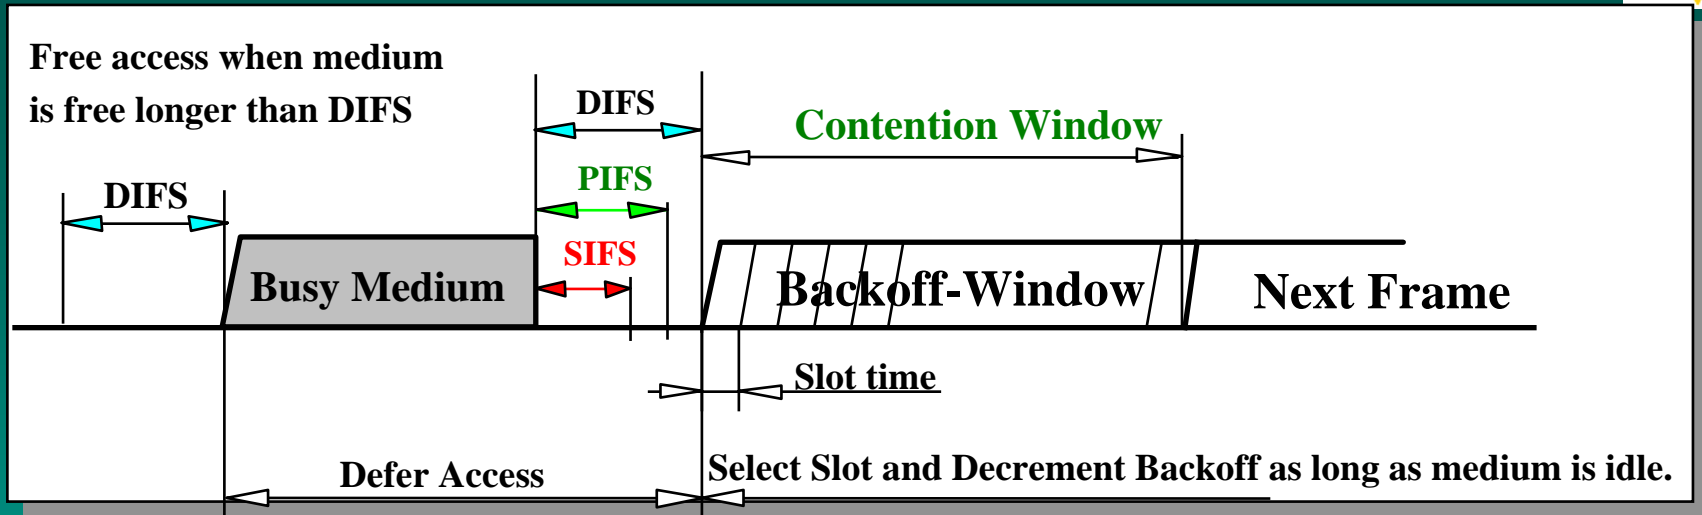

## Optional Point Coordination Function (PCF)

- **Contention Free Service uses Point Coordination Function (PCF) on a DCF Foundation.**
  - PCF can provide lower *transfer delay* variations to support *Time Bounded Services*.
  - Async Data, Voice or mixed implementations possible.
  - Point Coordinator resides in AP.
- **Coexistence between Contention and optional Contention Free does not burden the implementation.**

## Distributed Coordination Function

- ◆ Priority access to the wireless medium is controlled through the use of Inter-Frame Space ( IFS ) time intervals between the transmission of frames. Three IFS intervals are specified in the standard.
  - **Short-IFS ( SIFS )**
  - **Point Coordination Function-IFS ( PIFS )**
  - **Distributed Coordination Function-IFS ( DIFS )**

◆  $\text{Backoff Time} = \text{INT}(\text{CW} * \text{Random}()) * \text{Slot Time}$

CW = An integer between CWmin and CWmax

Random() = random number between 0 and 1

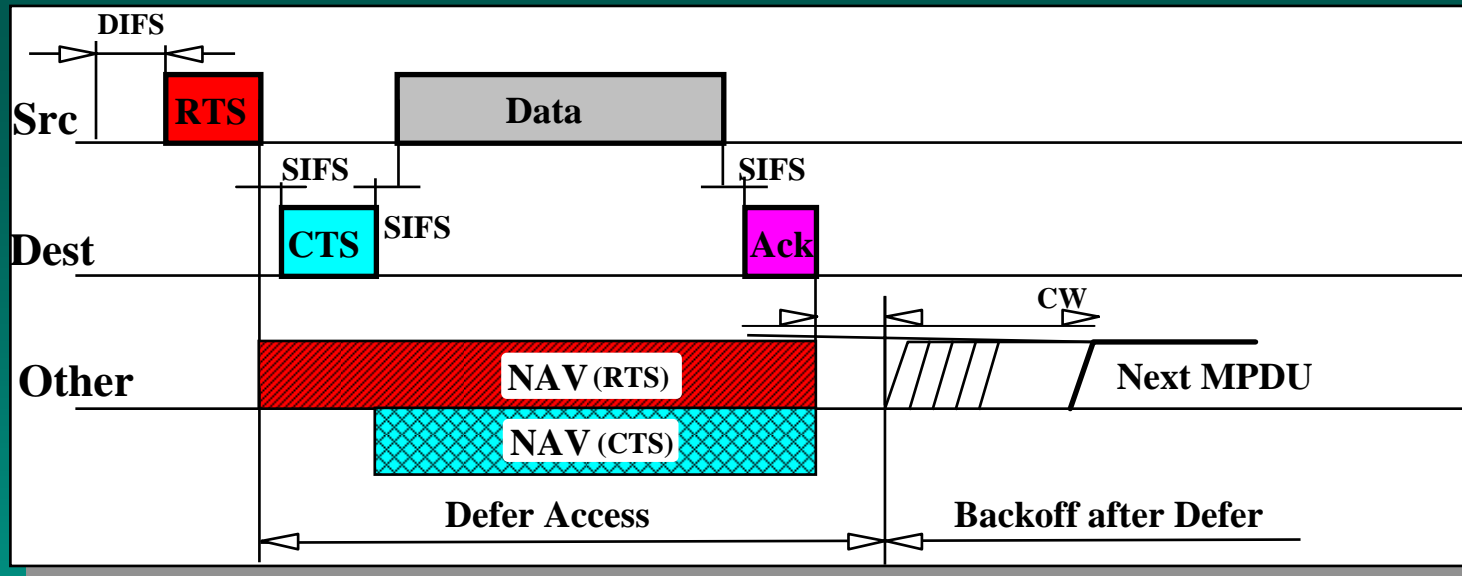

Slot Time = Transmitter turn-on delay +

medium propagation delay +

medium busy detect response time and is

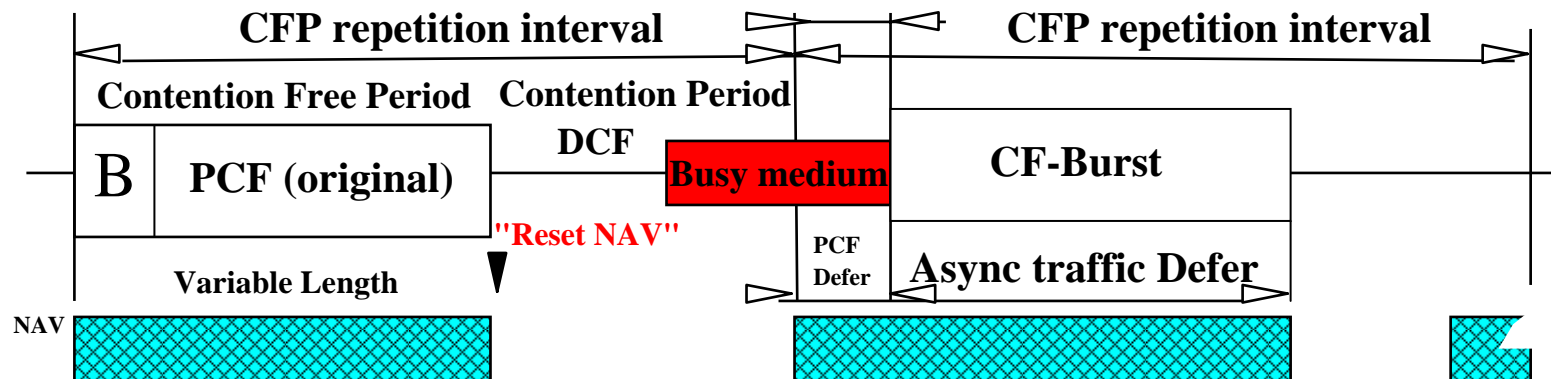

PHY dependent

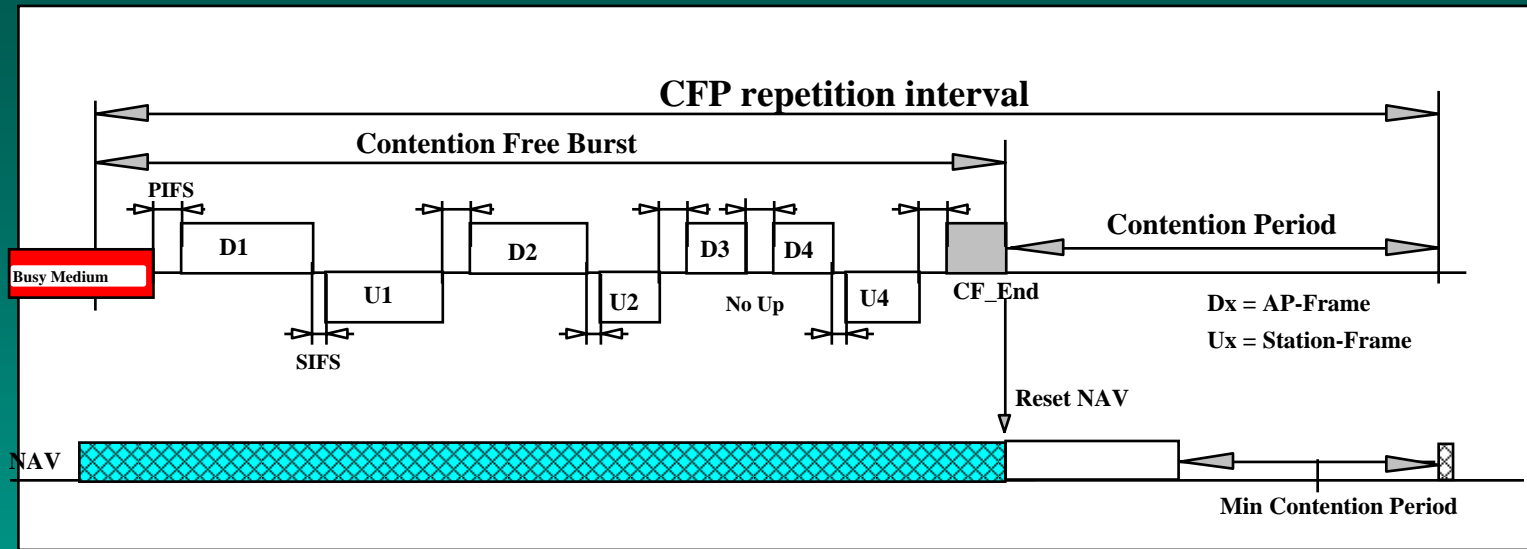

- **Duration** field in RTS and CTS frames distribute **Medium Reservation** information which is stored in a **Network Allocation Vector (NAV)**.
- Defer on either NAV or "CCA" indicating **Medium Busy**.
- Use of RTS / CTS is optional but must be implemented.

## PCF Defers for Busy Medium

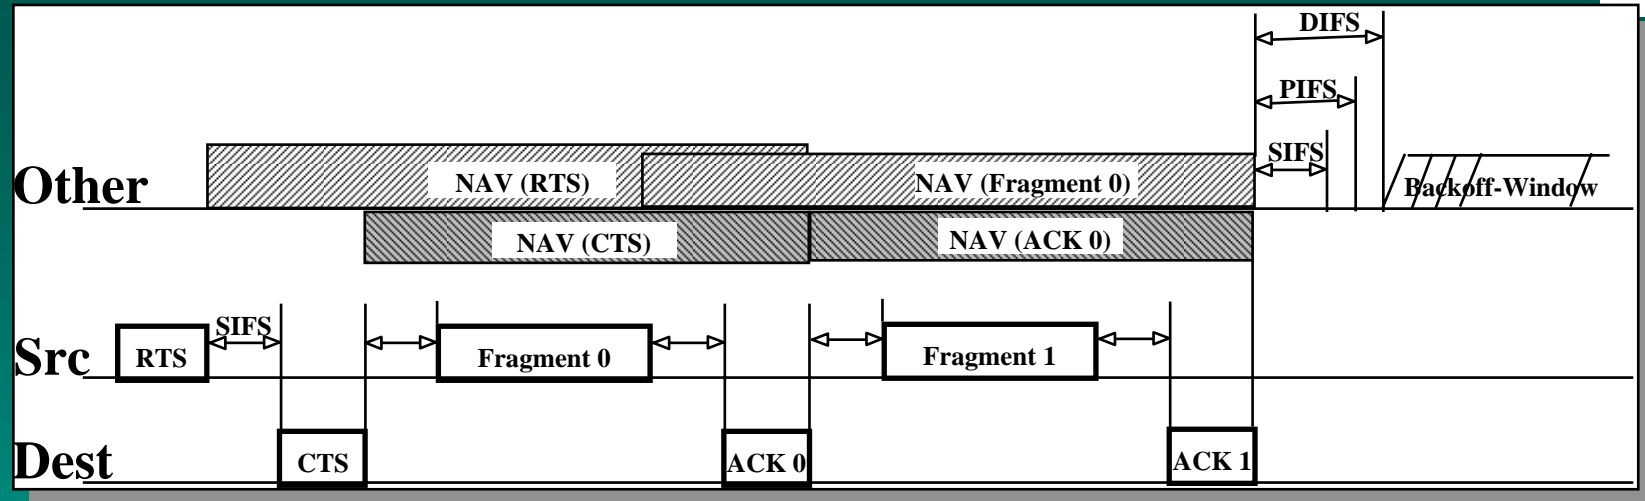

- Alternating *Contention Free* and *Contention* operation under PCF control.
- NAV prevents *Contention* traffic until reset by the last PCF transfer.
  - So variable length *Contention Free* period per interval.
- Both PCF and DCF defer to each other causing PCF Burst start variations.

- CF-Burst by Polling bit in CF-Down frame.
- Immediate response by Station on a CF\_Poll.
- Stations to maintain NAV to protect CF-traffic.
- Responses can be variable length.
- Reset NAV by last (CF\_End) frame from AP.
- "ACK Previous Frame" bit in Header.

# Fragmentation

- ◆ Burst of Fragments which are individually acknowledged.
  - **For Unicast frames only.**
- ◆ Random backoff and retransmission of failing fragment when no ACK is returned.
- ◆ *Duration* information in data fragments and Ack frames causes NAV to be set, for medium reservation mechanism.

# Power Management in IEEE 802.11

# Two types of power management

- ◆ Power management in an infrastructure network.
- ◆ Power management in an IBSS.

## In an infrastructure network

- ◆ STAs changing Power Management mode shall inform the AP of this fact using the Power Management bits within the Frame Control field of transmitted frames.
- ◆ The STAs that currently have buffered MSDUs within the AP are identified in a *traffic indication map* (TIM), which shall be included as an element within all beacons generated by the AP.
- ◆ A STA shall determine that an MSDU is buffered for it by receiving and interpreting a TIM.

## Cont.

- ◆ STAs operating in PS modes shall periodically listen for beacons, as determined by the STA's ListenInterval and ReceiveDTIMs parameters.
- ◆ If any STA in its BSS is in PS mode, the AP shall buffer all broadcast and multicast MSDUs and deliver them to all STAs immediately following the next Beacon frame containing a *delivery TIM* (DTIM) transmission.

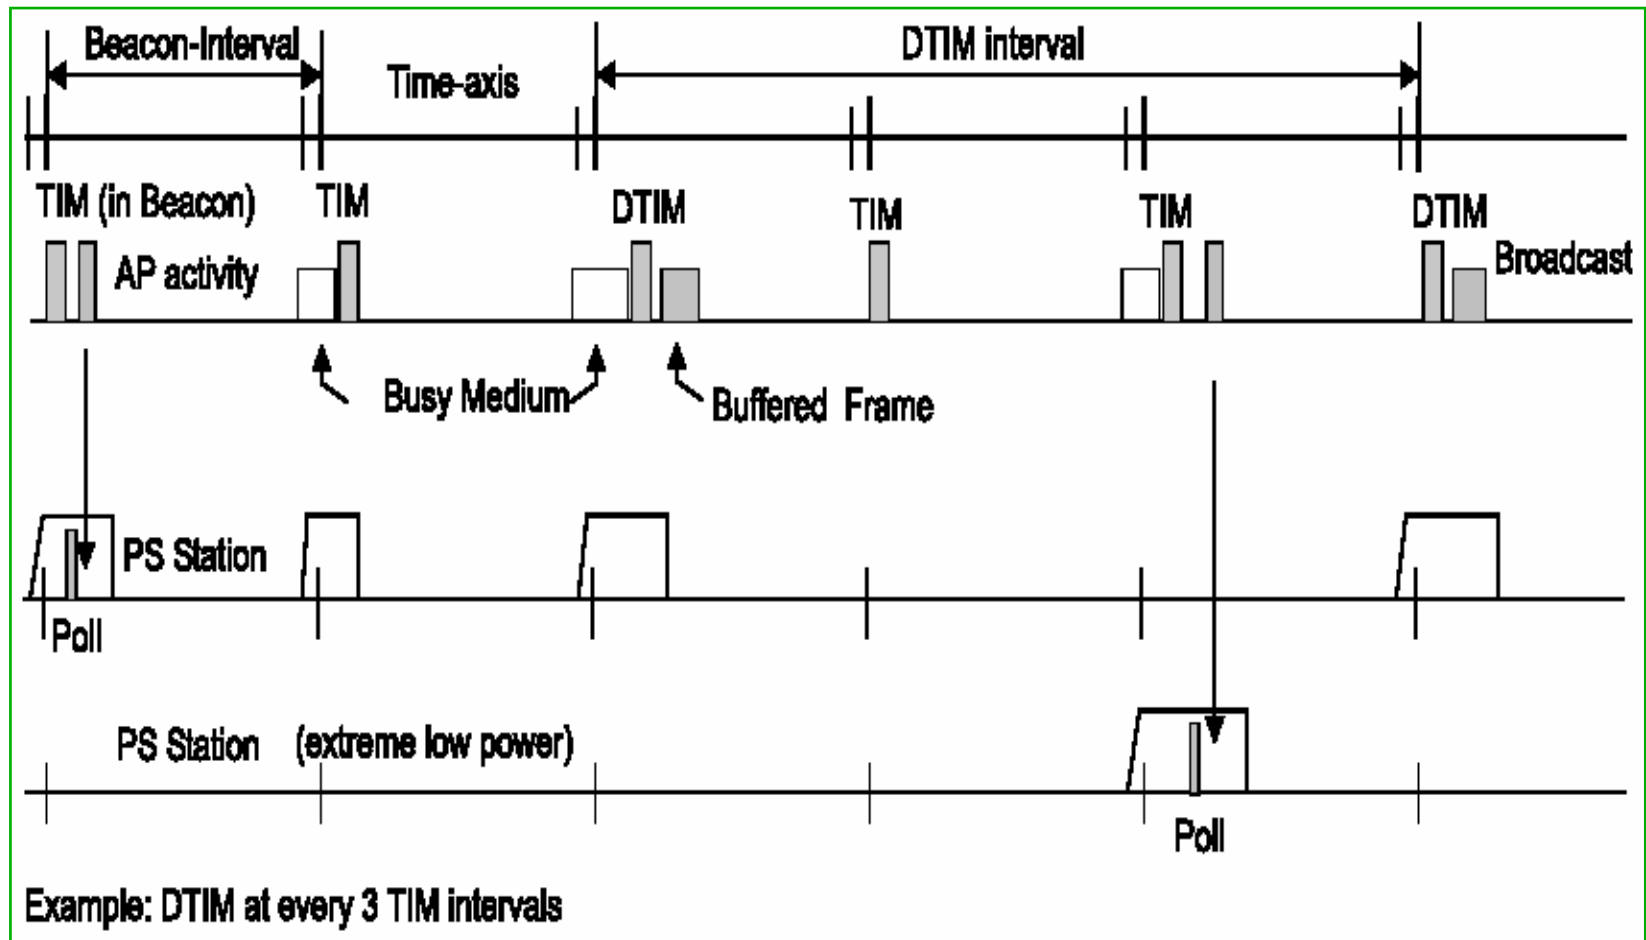

# STA Power Management modes

Active mode or AM	STA may receive frames at any time. In Active mode, a STA shall be in the Awake state. A STA on the polling list of a PCF shall be in Active mode for the duration of the CFP.
Power Save or PS	STA listens to selected beacons (based upon the ListenInterval parameter of the MLME-Associate.request primitive) and sends PS-Poll frames to the AP if the TIM element in the most recent beacon indicates a directed MSDU buffered for that STA. The AP shall transmit buffered directed MSDUs to a PS STA only in response to a PS-Poll from that STA, or during the CFP in the case of a CF-Pollable PS STA. In PS mode, a STA shall be in the Doze state and shall enter the Awake state to receive selected beacons, to receive broadcast and multicast transmissions following certain received beacons, to transmit, and to await responses to transmitted PS-Poll frames or (for CF-Pollable STAs) to receive contention-free transmissions of buffered MSDUs.

# AP TIM transmissions

- ◆ **The TIM shall identify the STAs for which traffic is pending and buffered in the AP.**
- ◆ **Every STA is assigned an Association ID code (AID) by the AP as part of the association process.**
- ◆ **AID 0 (zero) is reserved to indicate the presence of buffered broadcast/multicast MSDUs.**

# Infrastructure power management operation (no PCF operating)

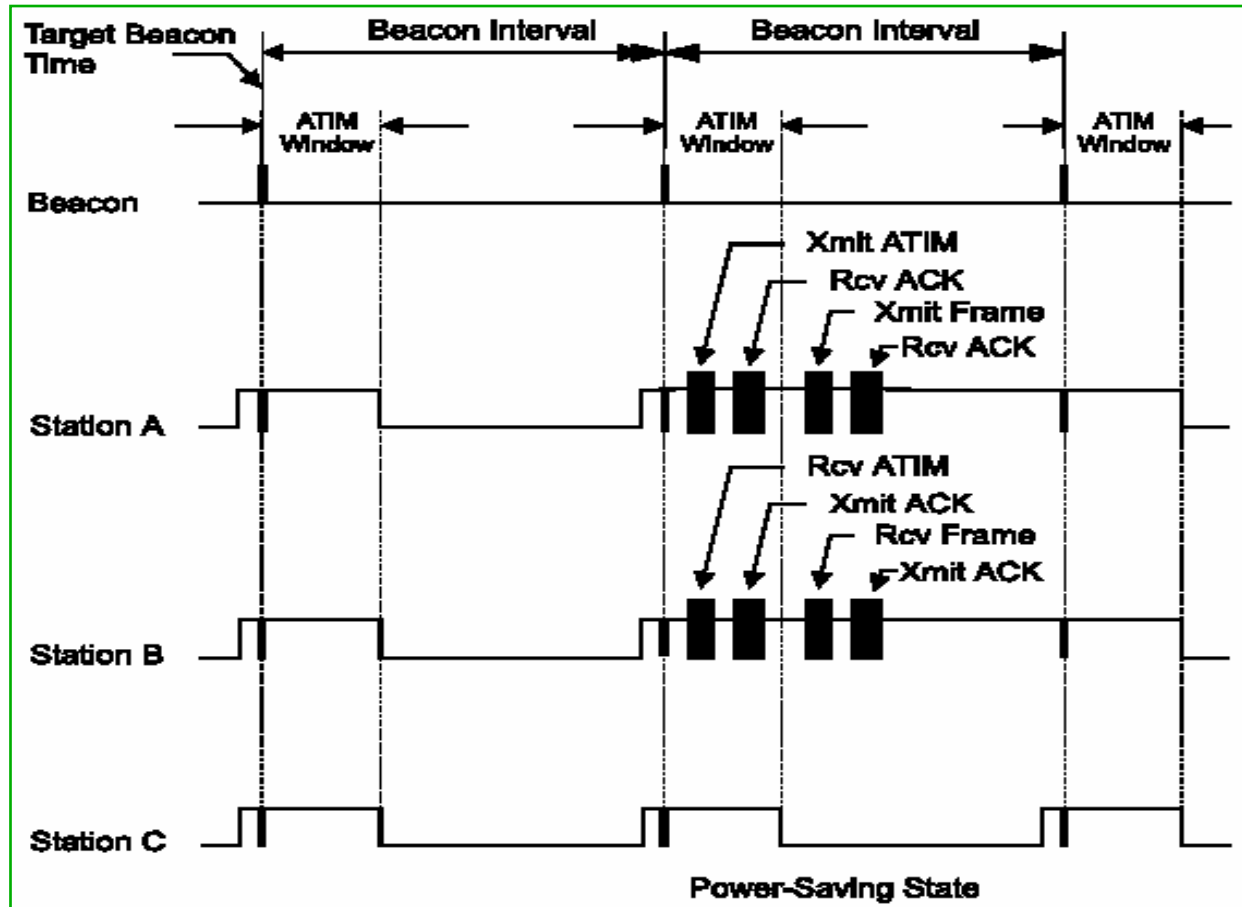

# AP aging function

- ◆ The AP shall have an aging function to delete buffered traffic when it has been buffered for an excessive period of time.
- ◆ The AP aging function shall not cause the buffered traffic to be discarded after any period that is shorter than the ListenInterval of the STA for which the traffic is buffered.
- ◆ The exact specification of the aging function is beyond the scope of this standard.

# Power management in an IBSS

- ◆ **The MSDUs that are to be transmitted to a power-conserving STA are first announced during a period when all STAs are awake.**
- ◆ **The announcement is done via an ad hoc traffic indication message (ATIM).**
- ◆ **A STA in the PS mode shall listen for these announcements to determine if it needs to remain in the awake state.**

# Power management in an IBSS—Basic operation

# Initialization of power management within an IBSS

- ◆ **A STA joining an existing IBSS shall update its ATIM Window with the value contained in the ATIM Window field of the IBSS Parameter Set element within the Beacon or Probe Response management frame received during the scan procedure.**
- ◆ **A STA creating a new IBSS shall set the value of the ATIM Window field of the IBSS Parameter Set element within the Beacon management frames transmitted to the value of its ATIM Window.**

## Cont.

- ◆ **The start of the ATIM Window shall be the TBTT, defined in 11.1.2.2. The end of the ATIM Window shall be defined as  $\text{TSF timer MOD BeaconInterval} = \text{ATIMWindow}$ .**
- ◆ **The ATIM Window period shall be static during the lifetime of the IBSS.**
- ◆ **An ATIM Window value of zero shall indicate that power management is not in use within the IBSS.**

# STA power state transitions

- ◆ If a STA is operating in PS mode, it shall enter the Awake state prior to each TBTT.
- ◆ If a STA receives a directed ATIM management frame containing its individual address, or a multicast ATIM management frame during the ATIM Window it shall remain in the Awake state until the end of the next ATIM Window.

## Cont.

- ◆ **If a STA transmits a Beacon or an ATIM management frame, it shall remain in the Awake state until the end of the next ATIM Window regardless of whether an acknowledgment is received for the ATIM.**
- ◆ **If the STA has not transmitted an ATIM and does not receive either a directed ATIM management frame containing its individual address, or a multicast ATIM management frame during the ATIM Window, it may return to the Doze state following the end of the current ATIM Window.**

# Introduction

## Background and motivation

- ◆ **GPRS(General Packet Radio Service) is designed for transmitting packet data and supposed to take its radio resource from the pool of channels unused by GSM voice services.**
- ◆ **Charging depending on the amount of data transmitted and the quality of service.**
- ◆ **Prepared for the hard competition within the future mobile telecommunications market.**
- ◆ **Bit rates of GPRS: nearly 170 kb/s**

# GPRS Architecture

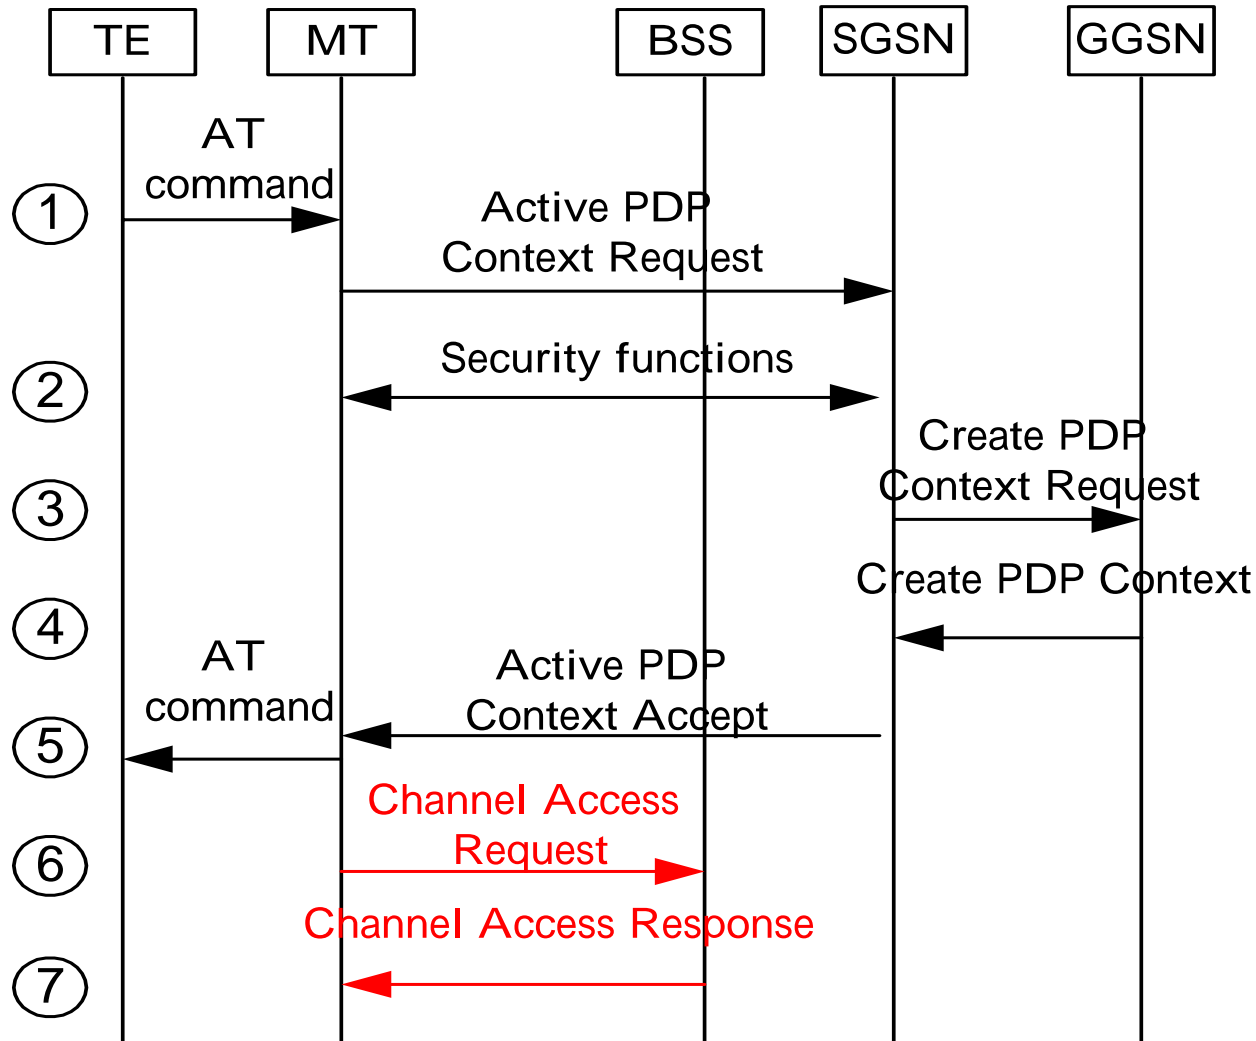

◆ Gateway GSN(GGSN)

- acts as logical interface to the external packet data networks and maintains routing information used to tunnel PDUs to the Serving GSN(SGSN) that is currently serving the MS.

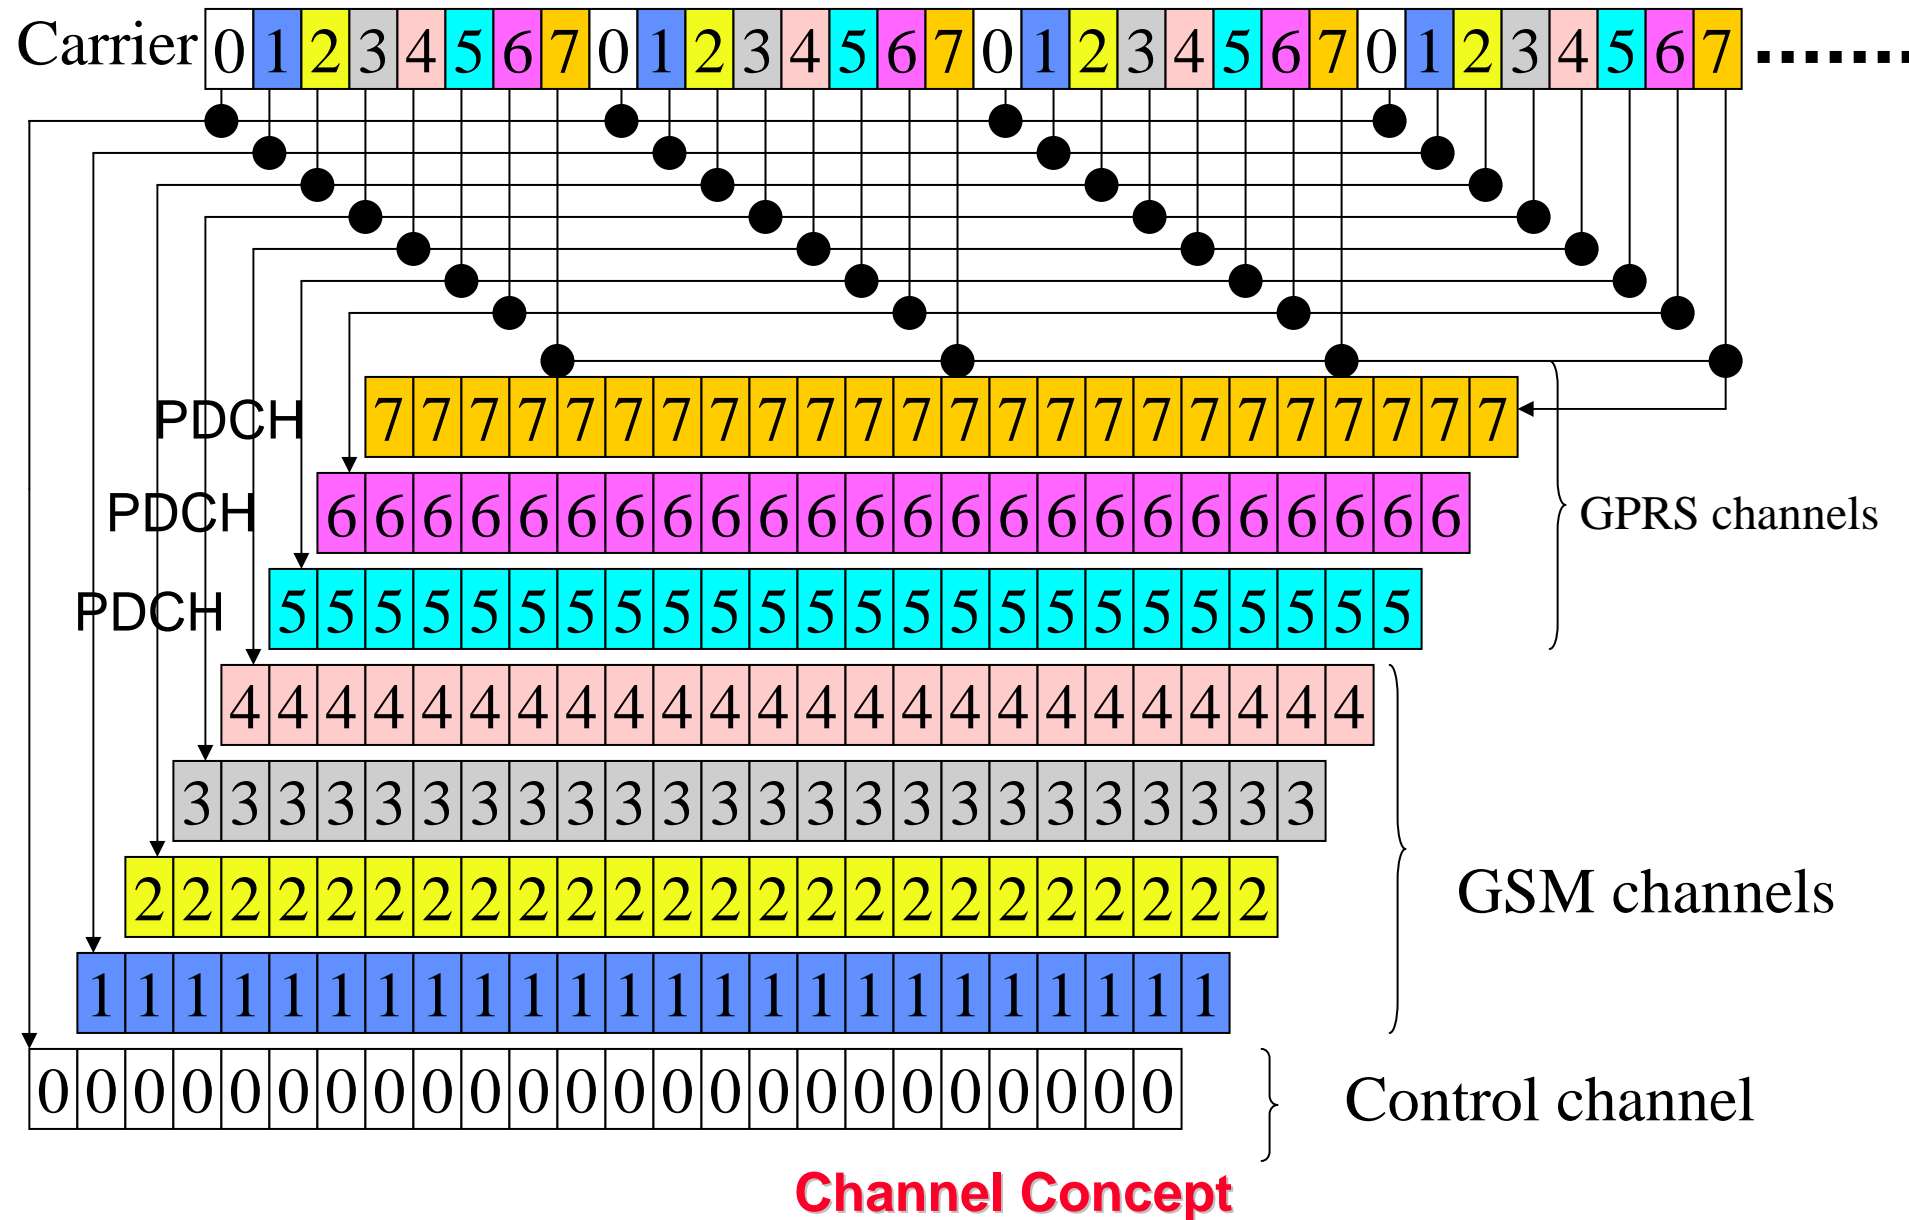

◆ Serving GSN(SGSN)

- is responsible for the delivery of packets to the MSs within its service area (mobile terminated transfer) and encapsulates the incoming packets and routes them to the appropriate GGSN(mobile originated transfer).

# The procedure to access GPRS service

# GPRS MAC Description

# GPRS MAC Description

- ◆ Channel Concept
  - The allocated PDCHs are logically grouped into master(MPDCHs) and slave channels (SPDCHs)

Group	Name	Direction	Function
PBCCH	PBCCH	DL	Broadcast
PCCCH	PRACH	UL	Random Access
	PPCH	DL	Paging
	PAGCH	DL	Access Grant
PTCH	PDTCH	DL/UL	Data
	PACCH	DL/UL	Associated Control

# GPRS MAC Description

## ◆ Model of Operation

- Each MAC frame is transmitted as one block of 4 consecutive TDMA slots

FH = Frame Header  
 FCS= Frame Check Sequence  
 BH = Block Header  
 BCS= Block Check Sequence

# GPRS MAC Description

- ◆ data transfer

## GPRS channel access mechanism

- **T:**The number of TDMA frames containing PRACH between initiation of the assignment procedure and the first access request message.
- **S:**the S and T are used to determine the next TDMA frame in which it may be allowed to make a successive attempt.

# GPRS MAC Description

- ◆ data transfer
  - Mobile Originated Transfer
    1. Packet transfer is initiated by a random access request (RA) on the PRACH that is determined by the USF sent on the corresponding downlink MPDCH.
    2. Channel reservation message including **temporary flow identity(TFI)** and **uplink status flag (USF)** coded by 3 bits is sent by the BTS.
    3. Blocks are sent according to descending order the BTS always knows how many blocks are still to be received and may adjust reservation scheduling.
